APPENDICES

1.0 Introduction

A second Value Engineering (VE) Study was held for the entire Portsmouth Bypass Project on December 3-6, 2007. This Study was based on the Stage 1 plans submitted by TranSystems. At this meeting, thirty VE Alternatives were identified as either a potential cost savings item or a design suggestion. ODOT reviewed each of these alternatives electing to implement three and instructed HDR Engineering, Inc. (HDR) to study four others for potential inclusion in Phase 1 of the project, which is under final design by HDR. This report summarizes HDR's study and findings of the following four VE Alternatives as they relate to Phase 1 (PID #19415):

- Alternative 2/30 – Adjust the profile to reduce the volume of excavation and waste material by allowing high fill culverts.
- Alternative 5 – Raise the culverts in high fill areas to shorten the pipe by filling in the upstream basin and constructing a lined channel down the fill slope.
- Alternative 11A/11B – Steepen the fill slopes by holding the toe of slope and extending the break point at the top of slope away from the centerline, or by holding the top of slope break point and bringing the toe in towards the centerline. The aforementioned method would reduce waste and the later method would reduce culvert length and stream impacts.
- Alternative 45/52 – Provide a crushed rock subgrade to minimize pavement thickness, reduce the number of underdrain runs required, and reduce the volume of waste material.

A benefit/cost ratio was generated for each of these alternatives utilizing the unit costs that were used by HDR for the Revised Stage 1 Cost Estimate dated July 2008. Each benefit/cost analysis compares the Stage 1 design to the alternative being studied. The following unit costs were used in this report:

Excavation	$ 3.35 per cubic yard
Embankment	$ 0.74 per cubic yard (avg. haul ½ mile)
Embankment	$ 0.85 per cubic yard (avg. haul 1¼ mile)
Waste Material	$ 1.10 per cubic yard
60" Culvert	$ 262.00 per linear foot
72" Culvert	$ 205.00 per linear foot
78" Culvert	$ 288.00 per linear foot
90" Culvert	$ 325.00 per linear foot
Stream Mitigation	$ 250.00 per linear foot
Asphalt Pavement	$ 102.00 per cubic yard
Type C Granular Matl.	$ 25.00 per cubic yard
Excavation, As Per Plan	$ 3.35 per cubic yard
Embankment, As Per Plan	$ 10.00 per cubic yard
6" Base Pipe UD	$ 4.05 per linear foot
6" Shallow Pipe UD	$ 4.25 per linear foot
6" Rock Cut UD	$ 5.75 per linear foot
Bridge Impacts	$ 72.00 per square foot (no add'l piers req'd.)

Each of the alternatives was studied as a stand alone measure. Care must be taken when combining the cost saving effects of two or more alternatives since the net savings may not equal the sum of the individual savings presented herein.

2.0 Alternative No. 2/30

2.1 Description

The purpose of this study was to investigate raising the profile in critical areas to reduce the volume of waste material by increasing the embankment volume and reducing the excavation volume. The ODOT Drainage Design Manual (General Notes – Figures 1008-10 through 1008-14) states that the maximum cover over any culvert is 100 feet, unless a special design is performed. The Stage 1 profile was set based on using standard culverts with a cover less than 100 feet. For this study, the requirement for using standard culverts has been waived.

2.2 Advantages / Disadvantages

The Value Engineering Report identified the following advantages/disadvantages:

Advantages:

- Reduces cost
- Improves the profile
- Reduces project cut and waste

Disadvantages:

- May require non-standard culverts
- Delays project schedule
- Increases design cost

2.3 Study Approach

The following parameters were established and used to develop alternative profiles:

- Design Speed of SR 823 is 70 mph
- Set reduction of excavation as target
- Minimize bridge impacts
- Minimize additional project footprint
- Use a maximum grade of 4.5% on SR 823
- Profile can change in key areas or throughout the complete Phase 1 limits
- Investigate options with and without bridge impacts

Utilizing these parameters, HDR developed eight conceptual profiles as alternatives. Two of these profiles (VE-1 and VE-2) were spot improvements focusing on the deep rock cut between stations 415+00 and 433+00 and did not impact the bridge structures. The other six profiles (VE-3 through VE-8) covered the majority of the Phase 1 limits. These profiles were developed using an iterative approach, modifying each subsequent profile to increase the earthwork savings while minimizing the increased structure cost. VE-7 and VE-8 provide the greatest potential earthwork cost savings and are presented in this report for consideration. The difference between VE-7 and VE-8 can be found in the grade north of TR234 through the first major cut, with VE-7 featuring a 2.9% grade and VE-8 using the maximum 4.5%. While the latter results in additional earthwork savings, it will impact the northern ramps for the TR234 Interchange. This impact will likely require additional acceleration length for the northbound on-ramp due to significantly slower truck speeds.

Since the vast majority of cross sections along SR 823 were modified by hand due to geotechnical design, HDR developed a simplified template (criteria file) within Geopak that could be easily processed for the alternative profiles. The simplified template was calibrated against the earthwork volumes from the Stage 1 plans until the margin of error was within one percent. Once calibrated, the simplified template was run for the alternative profiles. The comparison of earthwork volumes used the calibrated run versus the alternative runs. Calibration tables can be found in Appendix A for the presented profile alternatives (VE-7 and VE-8).

When developing the template in fill sections, barrier grading was used in lieu of safety grading in many locations. Most of the roadway is protected by guardrail in the Stage 1 plans, so safety grading was not required, and changing to barrier grading with the higher fills would limit the amount of additional impacts. The construction limits of the alternatives (VE-7 and VE-8) stay within the environmental footprint for the project and should have minimal impacts to the current right-of-way design; the exceptions are primarily at culvert locations where some additional right-of-way may be required. If a profile modification is implemented, the final design slopes can be refined as much as possible to use additional waste material while staying within the current right-of-way limits.

The culvert and stream impacts were estimated using the culvert drawings and raising the edge of the graded shoulder a distance equal to the alternative profile elevation minus the Stage 1 profile elevation. The proper side slope for the revised height of fill was then applied to the raised edge of graded shoulder and the culvert length revision was calculated. The stream impact equaled the change in culvert length.

The bridge impacts were calculated on an additional square foot of deck basis since no additional spans were required. The square footage was calculated by lengthening the bridge two times the difference in profile elevations on each end of the bridge. This represents the added bridge length to get the 2:1 spill slope in front of the bridge abutment.

The estimated engineering cost for all design changes was based on engineering judgment.

2.4 Benefit / Cost Analysis

The two profile alternatives with the greatest earthwork savings were carried into the benefit/cost analysis. Both Alternatives (VE-7 and VE-8) revise the majority of the Phase 1 profile length, with the difference between the two being the first major cut as described previously. See Appendix A for profile output data and profile drawings comparing Stage 1, VE-7 and VE-8 profiles. Also included in Appendix A are typical cross sections demonstrating the impact of raising the profile in key locations.

Both VE-7 and VE-8 present savings by reducing the excavation required and increasing the embankment, which reduces the waste material. The added costs associated with the alternatives include: increased embankment, culvert lengths, stream impacts, bridge lengths, wick drains, and engineering costs. Tables 2-1 through 2-4 show the estimated savings and costs associated with each alternative. Please note that the volumes shown in these tables do not include the side roads as they have not been modified as part of the profile changes and do not affect the cost comparison. For all earthwork volumes along the project, including side roads, see Table 2-5.

An additional cost feature with VE-8 is a change in the unit cost for embankment (from $0.74 / CY to $0.85 / CY). This is due to an increase in the average haul distance required to move material from excavation in one part of the project to where embankment is needed in another. A detailed analysis was undertaken that examined the location of the various cuts and fills and where material would need to be hauled. VE-8 requires a large amount of material to be moved from north of SR139 southward and across Swauger Valley Road, resulting in a significant increase in the average haul distance for the project. For VE-8, the average roundtrip haul distance is 1¼ miles, whereas both Stage 1 and VE-7 have an average roundtrip haul distance of approximately ½ mile.

Alternative VE-7

Table 2-1: New Profile Savings, Alt. 2/30 (VE-7)

Item	Stage 1 Calibrated	VE-7	Difference	Unit Cost	Savings
Excavation	5,351,000	4,498,000	853,000	$3.35	$2,858,000
Waste	2,922,000	1,569,000	1,353,000	$1.10	$1,488,000
				Total Excavation/Waste Savings	$4,346,000

Table 2-2: New Profile Cost, Alt. 2/30 (VE-7)

Item	Stage 1 Calibrated	VE-7	Difference	Unit Cost	Cost
Embankment	3,232,000	3,604,000	372,000	$0.74	$275,000
78” Culverts			24	$288.00	$6,912
72” Culvert			56	$205.00	$11,480
60” Culvert			39	$262.00	$10,218
48” Culvert			28	$139.00	$3,892
Stream Mitigation			147	$250.00	$36,750
Bridge Impacts					$305,000
Wick Drains					$616,000
Engineering					$500,000
				Total Cost	$1,768,000

As illustrated in the tables above, the benefit/cost ratio for VE-7 is 2.4. The total savings realized by implementing profile VE-7 is approximately $ 2.5 million.

Alternative VE-8

Table 2-3: New Profile Savings, Alt. 2/30 (VE-8)

Item	Stage 1 Calibrated	VE-8	Difference	Unit Cost	Savings
Excavation	5,351,000	4,264,000	1,087,000	$3.35	$3,641,000
Waste	2,922,000	345,000	2,577,000	$1.10	$2,835,000
				Total Excavation/Waste Savings	$6,476,000

Table 2-4: New Profile Cost, Alt. 2/30 (VE-8)

Item	Stage 1 Calibrated	VE-8	Difference	Unit Cost	Cost
Embankment	3,232,000	4,559,000	1,327,000	$0.85	$1,128,000
Embankment (uc Δ)*	3,232,000			$0.11	$356,000
78" Culverts			157	$288.00	$45,216
72" Culvert			225	$205.00	$46,125
60" Culvert			39	$262.00	$10,218
48" Culvert			28	$139.00	$3,892
Stream Mitigation			449	$250.00	$112,250
Bridge Impacts					$305,000
Wick Drains					$616,000
Extended Accel Lane					$200,000
Engineering					$500,000
				Total Cost	$3,323,000

* Denotes the change in unit cost from Stage 1 ($0.74) to VE-8 ($0.85) due to haul distance

As illustrated in the tables above, the benefit/cost ratio for VE-8 is 1.9. The total savings realized by implementing profile VE-8 is approximately $3.1 million.

2.5 Additional Information

There are elements to consider that can not be quantified in the benefit/cost analysis. Stream mitigation costs are included in the analysis; however, the value associated with an untouched natural stream has been forfeited. Another element to consider is the location of the environmental footprint and the construction limits. The construction limits for Alternatives VE-7 and VE-8 remain within the environmental footprint for the project and are anticipated to have minimal impacts to the current right-of-way design. The exception is at culvert or other locations where a 2:1 slope already exists and any profile change will push the new toe out of the Stage 1 construction limits.

The profiles of the northbound entrance ramp (Ramp A) and the southbound exit ramp (Ramp D) at the Shumway Hollow Road (TR234) Interchange will be impacted by the VE-8 profile. For earthwork calculations, a conceptual design was utilized for the revised ramp profiles. Due to the 4.5% mainline grade and steeper ramp grade required with VE-8, additional ramp acceleration length/auxiliary lane to the top of the hill may be required as significant slowing of truck traffic is likely due to the steeper grades. A lump sum cost has been included in the above analysis for an increased lane length. The potential negative impact to truck speed in this area should be taken into consideration when evaluating VE-8.

Currently the earthwork in the vicinity of the TR234 interchange north of TR234 will consist of staged embankment construction (two stages) with a maximum wick drain spacing of five feet in order to complete the earthwork in a two year construction schedule. This design was based on a maximum fill height of 57 feet. The proposed profiles VE-7 and VE-8 both increase the embankment height, with VE-8 increased to just less than 100 feet. Slope stability and wick drain analyses were performed with a maximum embankment height of 100 feet with 2:1 side slopes. With the new earthwork in this area, three stages will be required for embankment construction

with reduced wick drain spacing of four feet in order to complete the earthwork in a two year construction schedule. The cost shown in Tables 2-2 and 2-4 reflect the change in wick drain spacing from five feet to four feet. If VE-7 is selected for implementation, additional analysis would be undertaken to determine if up to five foot spacing could be used in all or part of the embankment. For the purposes of this study, the more conservative four foot spacing was utilized for both alternatives.

As mentioned previously, VE-8 would result in an increase in the average haul distance for the project. Shown in Table 2-5 is a breakdown of the cut and fill volumes along the project for each of the three distinct sections for Stage 1, VE-7 and VE-8. The table shows all earthwork volumes for the project, including side roads. This provides a snapshot of the amount of material in each section and how much would need to move between sections. As indicated in the table, the section from SR139 to CR28 features the greatest amount of waste for the project. Raising the mainline (and ramp) profiles at the CR28 interchange with VE-7 and VE-8 has provided over a 20% reduction in the amount of waste generated in this section. As with TR234, conceptual layouts of the revised CR 28 interchange ramp profiles were undertaken to determine the potential earthwork savings and feasibility of the profile change.

Table 2-5: Earthwork By Project Section

	Stage1		
	*Cut	Fill	Delta
Start to Swauger Valley	2,591,950	1,601,750	990,200
Swauger Valley to SR139	510,600	1,012,000	-501,400
SR139 to CR28	3,587,300	689,500	2,897,800
Total	6,689,850	3,303,250	3,386,600

	VE-7		
	*Cut	Fill	Delta
Start to Swauger Valley	2,319,350	1,731,650	587,700
Swauger Valley to SR139	377,200	1,157,000	-779,800
SR139 to CR28	3,019,900	789,550	2,230,350
Total	5,716,450	3,678,200	2,038,250

	VE-8		
	*Cut	Fill	Delta
Start to Swauger Valley	2,049,800	2,685,850	-636,050
Swauger Valley to SR139	377,200	1,157,000	-779,800
SR139 to CR28	3,019,900	789,550	2,230,350
Total	5,446,900	4,632,400	814,500

*Cut with 15% swell factor applied (payment is based on raw excavation)

Please note that profiles VE-7 and VE-8 are conceptual and may be modified slightly to maximize savings or minimize impacts once final cross sections are developed if either of these profiles were adopted into final design. Detailed design activities would also be required for the interchange

ramp profiles. Because neither profile VE-7 or VE-8 require a height of cover over the culverts greater than 100 feet, standard culverts can still be used on the project. In addition, if either VE-7 or VE-8 is incorporated into the final design, further savings may be achieved by shifting the southbound ramps at the CR 28 interchange toward the north to further reduce the amount of cut within this interchange. As more detailed interchange design would be required to determine any potential savings, it was not included as part of this VE Study.

Implementation of either VE-7 or VE-8 would require a design change to the Stage 1 plans, resulting in a schedule shift for the Stage 2 submission. This would ultimately impact the proposed letting schedule currently shown for 2011. A shift into the following calendar year would likely result in additional inflationary cost increases. If prompt decisions can be made throughout the process, design changes can likely be made in a timeframe that would keep the proposed letting schedule in the same calendar year (2011), thus minimizing or eliminating any inflationary increases.

3.0 Alternative No. 5

3.1 Description

The purpose of this study is to raise the culverts in high fill areas to shorten the pipe and construct a lined channel down the fill slope. In order to raise the culverts, the upstream flow line would need to be raised by filling the stream channel.

3.2 Advantages / Disadvantages

The Value Engineering Report identified the following advantages/disadvantages:

Advantages:

- Shortens culvert length
- Easier to replace culvert
- Reduces culvert cost
- Allows project waste to be placed in fills

Disadvantages:

- Requires maintenance of outlet ditch
- Increased stream impacts on inlet side
- Increased right of way impacts on inlet side

3.3 Study Approach

Each culvert was reviewed to determine if there were any constraints upstream or downstream that would prohibit raising the pipe. Three of the nine mainline culverts could not be raised due to invert elevation restraints. The culverts at station 466+45 and 473+92 have a pond at the upstream end that can not be filled. The invert of the culvert at station 535+50 is controlled by the upstream drainage on CR 28; therefore, this culvert can not be raised.

The remaining six culverts were investigated in more detail. The first step was to look at the controlling factors which determine how high the culverts could be raised. Since the premise was to fill the upstream channel, the control had to come from the SR 823 roadside ditch on the upstream side of the culvert. With the culvert naturally being the low point of the ditch, the control became the high points of the ditch on either side of the culvert. The high point was held in order to maintain the natural drainage patterns. The lower elevation of the two high points was used to calculate the new culvert elevation by providing a minimum 0.5% slope from the high point to the culvert invert. The characteristics of the stream were then checked to determine if achieving this invert was possible and if the stream would be the controlling factor in setting the invert elevation. Minimum cover requirements were also a determining factor in setting the invert elevation. See Appendix B for a schematic of this strategy. To maximize cost savings, a balance needed to be determined between shortening the culvert by raising it in the fill versus increasing right-of-way and mitigation impacts.

3.4 Benefit / Cost Analysis

Since none of the culverts in Phase 1 are special designs, the only savings in this study are reduced culvert length and reduced waste to fill in the upstream basin. The reduced waste quantity has been deemed negligible in regards to this study because for every cubic yard reduced waste

savings is an increase in fill cost. The unit cost for waste is $1.10 while the unit cost for fill is $0.74; therefore, each cubic yard of material used to fill in the upstream basin would only result in a $0.36 savings and without extremely deep culverts, the amount of fill is relatively small.

Table 3-1 shows the maximum savings in culvert length by raising the culvert as high in the fill as the controlling factors allow, which would give the maximum savings. Table 3-2 shows the additional cost in stream mitigation in order to raise the culvert in the fill.

Table 3-1: Culvert Savings, Alt. 5

Culvert	Culvert Size	Reduced Length	Unit	Unit Cost	Savings
353+88	72"	117	LF	$205	$23,985
364+36	72"	151	LF	$205	$30,955
375+08	90"	111	LF	$325	$36,075
404+06	78"	126	LF	$288	$36,288
412+07	72"	107	LF	$205	$21,935
504+60	60"	119	LF	$262	$31,178
Total					$180,000

Table 3-2: Mitigation Costs, Alt. 5

Culvert	Additional Length	Unit	Unit Cost	Cost
353+88	135	LF	$250	$33,750
364+36	300	LF	$250	$75,000
375+08	370	LF	$250	$92,500
404+06	690	LF	$250	$172,500
412+07	160	LF	$250	$40,000
504+60	315	LF	$250	$78,750
Total				$493,000

According to the tables, the benefit/cost ratio for this study is 0.4 resulting in an approximate cost of $313,000 to implement. This benefit/cost ratio does not include the additional cost of rock channel protection down the fill slope and the additional right-of-way required to fill in the upstream basin. Adding these values would only result in a higher cost to implement. In addition, the benefit/cost ratio does not exceed 1.0 for any of the individual culvert locations.

There are elements to consider that can not be quantified in the benefit/cost analysis. Stream mitigation costs are included in the analysis; however, the value associated with an untouched natural stream has been forfeited. Another element to consider is the location of the environmental footprint and the construction limits. Modifications associated with Alternative 5 stay within the environmental footprint for the project but will impact the current construction limits and right-of-way design on the upstream side of the culverts.

4.0 Alternative No. 11A/11B

4.1 Description

The purpose of this study is twofold. Alternative 11A intends to reduce the waste volume and maintain the construction limits by holding the Stage 1 toe of slope as a hinge point and using steepened fill slopes of 1½:1 at culvert locations in place of the current 2:1 slopes. Alternative 11B intends to reduce culvert and stream impact lengths by using the hinge point at the top of the current 2:1 design slope and using a 1½:1 slope in place of the current 2:1 slope. Both of these alternatives would require the use of processed durable rock to create the 1½:1 slope.

4.2 Advantages / Disadvantages

The Value Engineering Report identified the following advantages/disadvantages:

Advantages 11A:

- Allows project waste to be placed in fills
- Reduces cost

Disadvantages 11A:

- Special controlled fill (1½ :1)

Advantages 11B:

- Reduces length of culverts
- Reduces stream impacts
- Reduces right-of-way impacts
- Reduces cost

Disadvantages 11B:

- Creates additional waste material
- Special controlled fill (1½ :1)

4.3 Study Approach

Alternative 11A

Since the intent of this alternative was to use more waste in the fill slope areas without changing the toe of the slope location, there are no impacts to culvert length, stream mitigation or right-of-way. This alternative was investigated at the culvert locations in addition to all other fill areas along the project length. In areas where existing slopes are protected by guardrail the slopes were changed to 2:1, and at all culvert locations the slopes were changed to 1½:1. The only mainline culvert that did not have this slope change evaluated was the culvert at station 535+50 because it is located in close proximity to the structure over CR28.

Most fill slopes on this project follow safety grading criteria which requires a 6:1 or flatter foreslope through the clear zone and then a 3:1 or flatter slope beyond the clear zone. The Stage 1 design used 6:1 through the clear zone and 4:1 beyond the clear zone. In an effort to reduce waste, the intent of Alternative 11A was applied in all areas of fill with a 4:1 slope by changing the slope to 3:1 from the toe until meeting the 6:1 slope. This approach could be incorporated in the Stage 2 plans without implementing this Value Engineering Alternative. It is important to note however that

changing the slope design from the toe up will provide an inconsistent offset for the break from 6:1 to 3:1. The break will no longer be located at the clear zone offset and will vary from station to station. Although all break points will be located outside of the clear zone, this may create an unusual sight for drivers since the break line is not parallel to the edge of the shoulder.

The average end area method was used to determine the quantity of additional fill which equals the quantity of waste reduced. This method was used at the culvert locations in addition to the safety grading locations. Schematics and the average end area calculations for both these situations can be found in Appendix C.

Alternative 11B

This alternative holds the top of the current 2:1 as a hinge point and steepens the slope to 1½:1 which will bring the toe of slope in towards the centerline. This alternative actually increases the amount of waste; therefore, the only location that this alternative would result in a cost savings is at the culvert locations due to the reduction in culvert length, stream mitigation and right-of-way.

The average end area method was used to determine the quantity of fill reduced, which equals the quantity of additional waste. A schematic and the average end area calculations for this situation can be found in Appendix C. Each culvert location was evaluated to determine the length that the culvert could be reduced, which would equal the reduction in stream mitigation. Finally, the right-of-way impacts were investigated and found to be insignificant. Only a minimal reduction in right-of-way could be realized since the controlling points are typically located outside of the culvert locations.

4.4 Benefit / Cost Analysis

Alternative 11A

The savings associated with Alternative 11A came from the reduction of project waste. With this reduction comes an increase in fill material. Table 4-1 shows the values associated with each culvert. While the fill required in the 1½:1 slope is special controlled fill, the change in unit cost from regular fill has been deemed negligible due to the small fraction of total earthwork involved. Table 4-2 shows the values associated with the safety grading locations.

Table 4-1: Earthwork Cost / Savings at Culvert Locations, Alt. 11A

Culvert	Fill Vol. (CY)	Cost $0.74/CY	Waste Vol. (CY)	Savings $1.10/CY
353+88	1,280	$947	1,280	$1,408
364+36	4,090	$3,027	4,090	$4,499
375+08	8,130	$6,016	8,130	$8,943
404+06	15,530	$11,492	15,530	$17,083
412+07	13,420	$9,931	13,420	$14,762
466+45	58,620	$43,379	58,620	$64,482
473+92	32,830	$24,294	32,830	$36,113
504+60	2,520	$1,865	2,520	$2,772
Total	136,420	$101,000	136,420	$150,000

Table 4-2: Earthwork Cost / Savings at Safety Grading Locations, Alt. 11A

Street Name	Fill Vol. (CY)	Cost @ $0.74/CY	Waste Vol. (CY)	Savings @ $1.10/CY
SR823	240,340	$177,852	240,340	$264,374
TR234 Ramp A	9,400	$6,956	9,400	$10,340
TR234 Ramp B	2,760	$2,042	2,760	$3,036
TR234 Ramp C	900	$666	900	$990
TR234 Ramp D	1,470	$1,088	1,470	$1,617
CR28 Ramp A	600	$444	600	$660
Total	255,470	$189,000	255,470	$281,000

The total savings realized by Alternative 11A is $431,000 and the total cost associated with this savings is $340,000 (Embankment cost plus a $50,000 engineering cost). The resulting benefit/cost ratio is 1.3 resulting in a net savings of approximately $91,000.

Alternative 11B

The cost associated with Alternative 11B comes from the increase in project waste. With this increase comes a reduction in fill material. Table 4-3 shows the values associated with each culvert. While the fill required in the 1½:1 slope is special controlled fill, the change in unit cost from regular fill has been deemed negligible due to the small fraction of total earthwork involved.

Table 4-3: Earthwork Cost / Savings at Culvert Locations, Alt. 11B

Culvert	Fill Vol. (CY)	Savings $0.74/CY	Waste Vol. (CY)	Cost $1.10/CY
353+88	1,250	$925	1,250	$1,375
364+36	4,320	$3,197	4,320	$4,752
375+08	8,600	$6,364	8,600	$9,460
404+06	16,530	$12,232	16,530	$18,183
412+07	13,880	$10,271	13,880	$15,268
466+45	65,030	$48,122	65,030	$71,533
473+92	36,050	$26,677	36,050	$39,655
504+60	2,740	$2,028	2,740	$3,014
Total	148,400	$110,000	148,400	$163,000

The major savings associated with Alternative 11B comes from the reduction of culvert and stream mitigation length. Table 4-4 and Table 4-5 show the culvert and mitigation savings respectively.

Table 4-4: Culvert Savings, Alt. 11B

Culvert	Culvert Size	Reduced Length	Unit	Unit Cost	Savings
353+88	72"	32	LF	$205	$6,560
364+36	72"	43	LF	$205	$8,815
375+08	90"	76	LF	$325	$24,700
404+06	78"	57	LF	$288	$16,416
412+07	72"	75	LF	$205	$15,375
466+45	78"	148	LF	$288	$42,624
473+92	72"	149	LF	$205	$30,545
504+60	60"	36	LF	$262	$9,432
Total					$154,000

Table 4-5: Mitigation Savings, Alt. 11B

Culvert	Reduced Length	Unit	Unit Cost	Savings
353+88	32	LF	$250	$8,000
364+36	43	LF	$250	$10,750
375+08	76	LF	$250	$19,000
404+06	57	LF	$250	$14,250
412+07	75	LF	$250	$18,750
466+45	148	LF	$250	$37,000
473+92	149	LF	$250	$37,250
504+60	36	LF	$250	$9,000
Total				$154,000

The total savings realized by Alternative 11B is $418,000 and the total cost is $213,000 (Waste cost plus a $50,000 engineering cost). The resulting benefit/cost ratio is 2.0 resulting in a net savings of approximately $205,000. This benefit/cost ratio does not include the additional savings in right-of-way. Due to the nature of long right-of-way tangents, the shortening of the culverts will have a minimal impact on the right-of-way savings.

There are elements to consider that can not be quantified in the benefit/cost analysis. Both Alternative 11A and 11B utilize 1½:1 slopes. Some issues need to be considered when using this steep of a slope in high fill areas. The first issue is the above average inspection time to ensure the proper material and compaction is used for slope stabilization. The second issue is the negative visual effect (aesthetics) of a high rock slope that will grow little to no vegetation for many years. In addition, 1½:1 slopes were previously proposed in order to reduce costs at bridge locations, but it was ultimately decided by ODOT to maintain the 2:1 slopes as originally designed.

5.0 Alternative No. 45/52

5.1 Description

The purpose of Alternative No. 45 is to utilize durable rock from the project excavations to provide a layer of graded aggregate that can improve the strength of the subgrade, which would result in a reduced asphalt pavement thickness. The purpose of study 52 is to eliminate the underdrains at the outside edge of the traveled lanes. This study will incorporate both ideas into one set of analyses to reduce pavement and underdrain costs.

5.2 Advantages / Disadvantages

The Value Engineering Report identified the following advantages/disadvantages:

Advantages:

- Improves drainage of the subgrade
- Improves subgrade strength resulting in reduced pavement thickness
- Eliminates some underdrains
- Reduces cost

Disadvantages:

- Not a common department solution
- Increases construction management effort
- Possible learning curve for unfamiliar contractors

5.3 Study Approach

The first step in this study was to determine the amount of durable rock available from the project excavations that could be used for the aggregate base. The total volume of rock excavation was determined by the average end area method in proposed rock cut locations. Based on test borings performed at various locations within these cuts, approximately 75% of the rock cut excavation is anticipated to be comprised of sandstone. Table 5-1 shows the estimate of total durable rock available. The Sandstone Volume is 75% of the Cut Volume listed in the table.

Table 5-1: Durable Rock Available, Alt. 45/52

Street Name	Begin Station	End Station	Cut Vol. (CY)	Sandstone Vol. (CY)
SR823	415+50	433+50	1,269,500	952,100
SR823	449+50	457+50	305,400	229,100
SR823	479+50	482+75	88,200	66,200
SR823	497+75	503+50	247,400	185,600
SR823	508+50	528+00	1,680,900	1,260,700
TR234	18+00	26+00	340,800	255,600
TR234 - Ramp D	385+00	387+00	55,700	41,800
CR28 - Ramp A	519+00	528+00	413,800	310,400
CR28 - Ramp B	523+50	527+00	68,300	51,200
CR28 - Ramp C	522+00	528+00	213,600	160,200
CR28 - Ramp D	520+00	526+50	326,000	244,500
Total				3,757,000

Since it is anticipated that a large portion of the savings under this alternative would come from reducing the pavement thickness, a potential new pavement buildup was determined for the project. The Stage 1 pavement buildup for SR 823 is 11" of 880 Warranty Pavement on 6" of Aggregate Base with underdrains at the edges of pavement, edges of shoulder and median. Currently TR 234 ramps and CR 28 ramps have 9" of 880 Warranty Pavement on 6" of Aggregate Base with underdrains at the edges of shoulder. The ODOT Pavement Design & Rehabilitation Manual was used to determine the current structural number of 5.0 for the SR 823 pavement section. The calculation to determine a proposed pavement buildup that provides an equal structure number can be found in Appendix D. HDR chose to use a minimum pavement buildup of 8" of 880 Warranty Pavement on 6" of Aggregate Base on 12" of Type C Granular Material for SR 823, TR 234 ramps and CR 28 ramps. This minimum pavement section provides a higher structural number than the Stage 1 pavement section, but was held as a minimum for serviceability reasons. Underdrains were considered only at the edges of shoulder to collect any water within the aggregate base and the Type C Granular Material. This typical section provides adequate pavement structural stability and subgrade drainage. It was determined that there is adequate durable rock through excavation to supply the Type C Granular Material for a 12" lift throughout the project limits.

The new pavement buildup was analyzed to determine the cost and savings associated with the design change. The project was divided into three typical sections: fill, cut and rock cut. The quantities for each typical section were impacted differently by the change in pavement design. In addition, locations where the earthwork will be constructed but not paved until later design phases (SR 823 Station 352+00 to 396+50, TR 234 ramps B & C, SR 823 Station 520+00 to 537+00 and CR 28 ramps B & C) will also be impacted differently by the change in pavement design. There are six different scenarios that were analyzed. Typical sections and a written description of each scenario can be found in Appendix D.

5.4 Benefit / Cost Analysis

The majority of savings in this study came from the reduced pavement thickness and the removal of the majority of underdrains. The major cost of this study is the Type C Granular Material required for the new drainage layer under the pavement. The Type C Granular Material will be processed on site from the sandstone excavated for the project. There are other costs and savings regarding different changes in earthwork quantities, but they are minimal in comparison to the Type C Granular Material, reduced pavement and reduced underdrains. Table 5-2 and Table 5-3 show the results of the benefit/cost analysis based on the six typical section scenarios applied to their applicable station ranges.

Table 5-2: New Pavement Design Savings, Alt. 45/52

Item	Quantity	Unit	Unit Cost	Savings
Reduced Pavement	11,100	CY	$102.00	$1,132,200
Reduced Fill	36,400	CY	$0.74	$26,936
Reduced Waste	11,100	CY	$1.10	$12,210
Reduced Cut APP	6,800	CY	$3.35	$22,780
Reduced Embankment APP	26,700	CY	$10.00	$267,000
Reduced 6" Base Pipe Underdrains	7,500	LF	$4.05	$30,375
Reduced 6" Shallow Pipe Underdrains	21,350	LF	$4.25	$90,738
Reduced 6" Rock Cut Underdrains	16,800	LF	$5.75	$96,600
			Total Savings	$1,679,000

Table 5-3: New Pavement Design Cost, Alt. 45/52

Item	Quantity	Unit	Unit Cost	Cost
Type C Granular Material	50,600	CY	$25.00*	$1,265,000
Additional Cut	8,600	CY	$3.35	$28,810
Additional Waste	21,000	CY	$1.10	$23,100
Engineering				$100,000
			Total Cost	$1,417,000

According to the tables, the benefit/cost ratio of this alternative is 1.2 resulting in an approximate savings of $262,000.

* To determine the unit cost of the Type C Granular Material, the quantities and associated unit costs were reviewed from ODOT bid tabulations from 2003 through 2007. As very little data was available for Type C Granular Material, the data set was expanded to include both Type B and Type D Granular Material. The bid quantities were plotted against their associated unit cost to determine the relationship between project size and unit cost. A power function was then fit to the data in order to determine an average unit cost for the approximate 50,000 cubic yards (CY) of granular material, resulting in a unit cost of $22.50/CY. Bringing this amount forward to 2008 dollars results in a unit cost of $25.00/CY. While on site processing may result in a lower unit cost, for this study a conservative approach was utilized so as to not over estimate potential savings.

6.0 VE Studies Summary

This report presents the results of an engineering study for the four value engineering alternatives identified by ODOT to determine their feasibility for inclusion in the SCI-823-6.81 (Portsmouth Bypass, Phase 1) project. The report presents the benefit/cost ratio and net savings for each alternative. These alternatives were analyzed individually as stand alone measures. Care must be taken when combining the cost saving effects of two or more of the alternatives since the net savings may not equal the sum of the individual savings presented herein.

It should also be understood that while the analyses presented herein were thorough, they do not represent final design cost analyses. When reviewing the savings and costs presented in this report, the magnitude of the numbers are what is important. The exact numbers may change if any of these alternatives are incorporated into the final design of the project, based on a more detailed design. In general, a conservative approach was undertaken so as to not over estimate any potential cost savings.

Table 6-1 is a summary of each alternative with their benefit/cost ratio and the estimated net savings.

Table 6-1: Value Engineering Study Results

Alternative	Description	Benefit/Cost	Estimated Savings
2/30	Revised Profile VE-7 Revised Profile VE-8	2.4 1.9	$2,500,000 $3,100,000
5	Raise Culverts	0.4	$313,000*
11A	Steepen Slope/Hold Toe	1.3	$91,000
11B	Steepen Slope/Hold Top	2.0	$205,000
45/52	Rock Subgrade	1.2	$262,000

* This alternative presents a net increase in project costs.

Appendix D – Alternative No. 45/52 Supporting Material

VE Study 45/52 - Pavement Reduction By Using Crushed Rock SubBase

Structural Coeffients from Fig. 401-1 in the Pavement Design Manual

Item	Description	Coefficient	
Item 880	Warranty Pavement, Top 3"	0.43	
Item 880	Warranty Pavement,Below Top 3"	0.36	
Item 304	Aggregate Base	0.14	
	Crushed Rock (Granular Material, Type C)	0.11	use 0.11 as granular subbase (per AASHTO)

Current Design As Per Stage 1 Plans

Item	Description	Coefficient	Thickness	SN
Item 880	Warranty Pavement, Top 3"	0.43	3	1.29
Item 880	Warranty Pavement,Below Top 3"	0.36	8	2.88
Item 304	Aggregate Base	0.14	6	0.84
			SN =	5.01

Minimum Pavement Section Desired

Item	Description	Coefficient	Thickness	SN
Item 880	Warranty Pavement, Top 3"	0.43	3	1.29
Item 880	Warranty Pavement,Below Top 3"	0.36	5	1.8
Item 304	Aggregate Base	0.14	6	0.84
			SN =	3.93

Required SN for the Crushed Rock subbase

5.01
-3.93
1.08

Required Thickness of Crushed Rock

1.08 Divided By 0.11 = 9.82 inches

Use 12 inches of Granular Material, Type C
(set 12 inches as the minimum value)

Savings **3** inches of Asphalt

Cost **12** inches of Granular Material, Type C

VE Study 45/52 – Typical Section Descriptions

Fill Sections with Pavement

SR823
Asphalt: 3" Savings
Waste: 3" Savings
