## Executive Summary

The Ohio Department of Transportation (ODOT) is planning to convert 14.78 miles of existing United States (US) 33 in Meigs County, Ohio from a two-lane highway to a four-lane divided highway by adding a median and two lanes north of the existing alignment. Stantec Consulting Services Inc. (Stantec) has been contracted by ODOT to perform engineering and design services for the eastern portion of the project, which is approximately 10 miles long. Historical geotechnical records were primarily used for current project geotechnical recommendations; however, a geotechnical exploration was needed to provide recommendations for three new companion bridges for US 33 over Bowman's Run, Old Town Creek, and a tributary of Old Town Creek. Borings were also advanced near wet areas planned for fill north of the existing two-lane alignment, identified during a site reconnaissance performed by others during previous phases of work. During a later phase of drilling, additional borings were performed along cut slopes to fill data gaps and to obtain undisturbed samples for one-dimensional consolidation testing.

Stantec advanced 19 borings near the proposed bridge foundation locations, wet areas planned for fill and cut slopes. Moderate and low plasticity fine-grained soils were encountered in all borings. The soils encountered were silt and clay (A-6a), silty clay (A-6b), clay (A-7-6), sandy silt (A-4a), silt (A-4b), and gravel and stone fragments with sand, silt, and clay (A-2-6). The soils were described as medium stiff to hard and damp to moist. Rock coring was performed in all eight bridge borings and five cut slope borings. Sandstone interbedded with shale was encountered in seven of the eight bridge borings, while claystone and shale were encountered in three of the eight bridge borings. Cut slope borings encountered shale followed by interbedded shale and sandstone and either sandstone or shale.

It is recommended that the bridge abutments and/or piers for the bridges be supported by drilled shafts bearing on bedrock. Bridge seismic site classifications varied between Seismic Site Class C and Seismic Site Class D. More detailed recommendations for the bridges are included within this report.

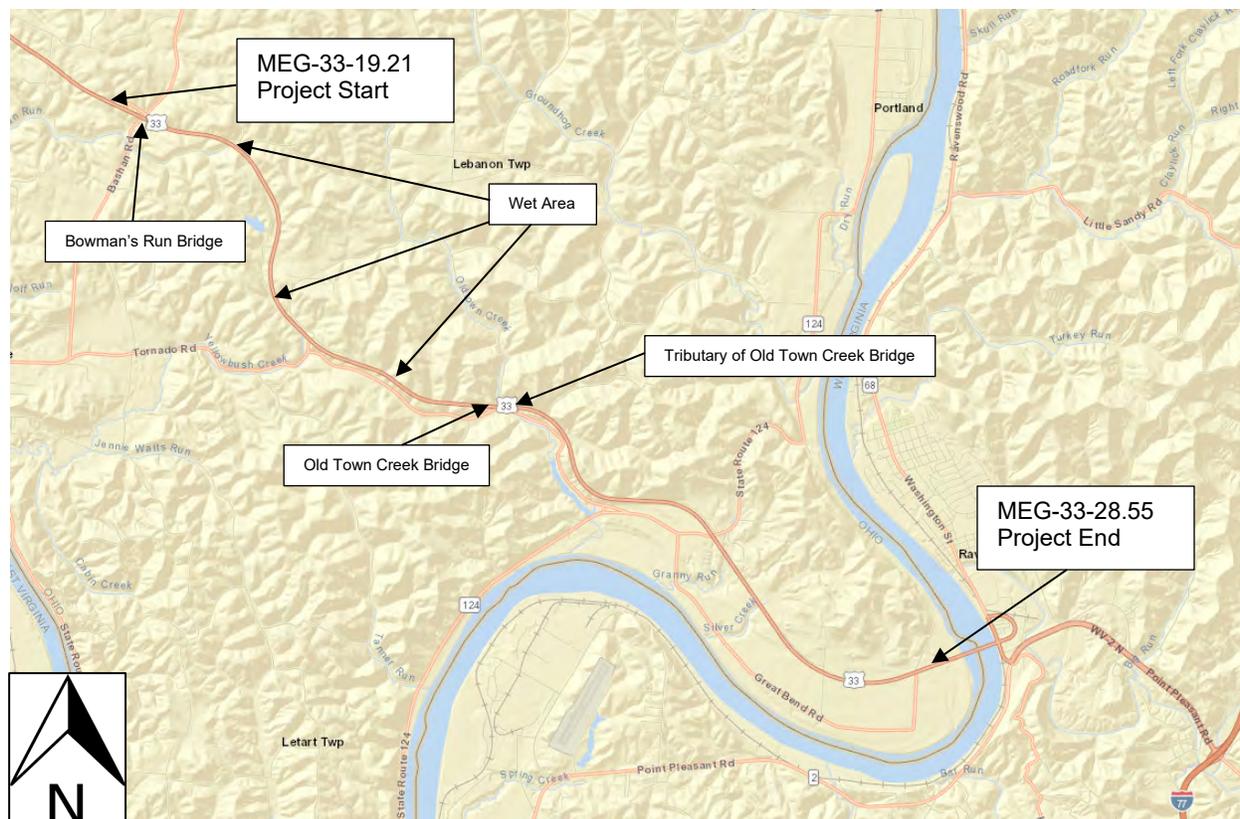

New roadway embankments will be constructed for this project, along with areas of cut excavations. Stability analyses were performed for the proposed embankments. For embankments taller than 25 feet, 3H:1V (horizontal to vertical) slopes are suggested to meet minimum factors of safety. Using less conservative shear strength parameters (as recommended in the ODOT Geotechnical Design Manual (GDM)) for the proposed embankment indicates that 2H:1V slopes can be used if necessary for taller slopes. Reinforced soil slopes can be used for slopes steeper than 3H:1V to achieve minimum factors of safety assuming more conservative shear strength parameters (as used in historic stability analyses) for the proposed embankment material.

Roadway cut slopes were designed using slopes of 2H:1V for shale, claystone and mudstone and 1H:1V for sandstone. The slopes were designed with 15-foot-wide horizontal benches on taller cuts to slow water flow down the slope. The benches were positioned at the bases of more durable bedrock layers where possible to resist the undercutting of the more durable rock over time.

A subgrade analysis was performed in general accordance with ODOT GDM based on dynamic cone penetrometer (DCP) tests and shallow profile borings performed along the alignment by others in April 2023. The DCP testing indicates that subgrade stabilization may be necessary from approximately Station 1305+00 to 1343+00, but only where less than 3 feet of cut or fill is planned. As such, 12 inches of subgrade stabilization should be assumed for about 10 percent of this station range that consists of several deep cuts and fills not requiring stabilization.

## 1.0 INTRODUCTION

The Ohio Department of Transportation (ODOT) is planning to convert 14.78 miles of existing United States (US) 33 in Meigs County, Ohio from a two-lane highway to a four-lane divided highway by adding a median and two lanes north of the existing alignment. Stantec Consulting Services Inc. (Stantec) has been contracted by ODOT to perform engineering and design services for the eastern portion of the project, which is approximately 10 miles long. Historical geotechnical records were primarily used for geotechnical recommendations for the project; however, an additional geotechnical exploration was performed to obtain subsurface information for three new companion bridges for US 33 over Bowman’s Run, Old Town Creek, and a tributary of Old Town Creek. Borings were also advanced near wet areas planned for fill north of the existing two-lane alignment which were identified during a site reconnaissance performed by others during previous phases of work. During a later phase of drilling, additional borings were performed along cut slopes to fill data gaps and to obtain undisturbed samples for one-dimensional consolidation testing. Figure 1 shows the overview of the portion of US 33 being widened to four lanes and the aforementioned existing bridge locations.

## 2.0 GEOLOGY AND OBSERVATIONS OF THE PROJECT

### 2.1 GENERAL

The *Physiographic Regions of Ohio Map* (Ohio Department of Natural Resources (ODNR), 1998) indicates that the project site is located within the Marietta Plateau region. The region is described as a dissected plateau with high relief (generally 350 feet up to 600 feet) near the Ohio River containing mostly fine-grained rocks. Red shales, red soils, and landslides are relatively common. Elevations typically range from 515 to 1,060 feet.

### 2.2 SOIL GEOLOGY

According to the *Ohio Geology Interactive Map* (ODNR, 2024), the project site is primarily underlain by Cenozoic colluvium from the Holocene age, underlain by lacustrine deposits from the early to middle Pleistocene age and outwash from the late Wisconsinan age. The USDA web soil survey (2023) indicates that approximately 40 percent of the project site is underlain by the Upshur-Gilpin complex. These soils are typically well drained with a moderately low to moderately high capacity to transmit water. The typical profile consists of 1 inch of slightly decomposed plant material, 5 inches of silt loam, 28 inches of silty clay loam, 3 inches of very channery silty clay loam, and 10 inches of bedrock. The remaining soil types make up 5 percent or less of the project site according to the web soil survey. The project is located in an unglaciated region of Ohio; however, the *Ohio Geology Interactive Map* suggests the far southern portion of the site situated within the Ohio River valley has a drift thickness of up to 120 feet.

### 2.3 BEDROCK GEOLOGY

Bedrock mapping (*Ohio Geology Interactive Map* [ODNR, 2023]) indicates that the majority of the site is underlain by sedimentary bedrock from the Dunkard and Monongahela Groups of the Permian and Pennsylvanian ages. Bedrock of the Dunkard Group typically consists of shale, siltstone, and sandstone with lesser amounts of limestone and coal. The bedrock is described as brown, gray, red, and green with thicknesses ranging from 500 to 600 feet. Bedrock of the Monongahela Group typically consists of shale, siltstone, limestone, sandstone, and coal. The bedrock is described as gray, green, and infrequently red with thicknesses over 350 feet.

According to the *Ohio Oil and Gas Well Viewer* map (ODNR, 2023), there are six wells located near the current alignment of US 33. Well logs indicate sandstone, shale, limestone, and dolomite bedrock are present in the area. One log at the far southern region of the site location indicates a bedrock depth of 129 feet.

According to the *Ohio Mine Locator* (ODNR, 2023), there are no active or inactive mines within the project footprint. The *Karst Interactive Map* (ODNR, 2023) indicates there are no known karst features in Meigs County.

### 2.4 HYDROLOGY

The three bridges at the site cross Bowman's Run, Old Town Creek, and a tributary to Old Town Creek. Bowman's Run flows west into the Ohio River near Racine, Ohio. Old Town Creek flows south into the Ohio River near Rolandus, Ohio.

## 2.5 HYDROGEOLOGY

According to the *Ohio Geology Interactive Map* (ODNR, 2023), bedrock aquifers at the project site yield less than 5 gallons of water per minute. The far southern portion of the site is located in the Ohio River Valley Fill Aquifer, which typically yields over 500 gallons of water per minute. The thickness of this sand and gravel aquifer ranges from 25 to 100 feet.

A search was performed using the ODNR Ohio Water Wells Map (2023) to determine if any water wells are located near the project site. According to the map, 35 water wells have been drilled near US 33 in the project area. The well logs indicate bedrock was encountered at depths ranging from 3 to 92 feet and the static water was encountered at depths varying from 5 to 80 feet.

## 2.6 SEISMIC

A review of the seismic data available in the project vicinity was completed using the *ODNR Ohio Earthquake Epicenters Map* (2023). Overall, Ohio has a relatively limited amount of seismic activity. Within a radius of 10 miles from the center of the project site, four earthquake epicenters have been recorded. The magnitudes of these earthquakes range from 1.6 to 2.8. The available data reviewed included events that occurred in Ohio from 1936 to present day.

## 2.7 SITE RECONNAISSANCE

Stantec representatives visited the site from November 27 to 29, 2023 to examine field conditions, road conditions, embankment conditions, and to mark boring locations. The land surrounding the project site can be described as rural and agricultural. In general, the existing embankments were observed to be in fair condition. Wet areas, standing water, surface erosion, erosion gullies, areas of exposed geo-fabric/geo-mesh, and damaged culverts were observed south of the existing embankments. Pavement conditions were generally fair throughout the site; however, conditions were poor to fair between approximate mile markers 25.00 and 28.80. A memo summarizing the inspection findings was provided to the District on December 21, 2023. Stantec representatives visited the site again on September 9, 2024 to mark borings for cut slope sections and offset structure borings to obtain samples for consolidation testing.

## 3.0 EXPLORATION

### 3.1 HISTORIC EXPLORATION PROGRAMS

The ODOT Traffic Information Management System (TIMS) provided documentation for the original investigations for MEG-124-26.66 and MEG-124-31.57, both now US 33, completed in 1999. Soils encountered during these explorations were classified or described as clay (A-7-6), sandy silt (A-4a), silty clay (A-6b), and silt and clay (A-6a). A considerable amount of silt (A-4b), coarse- and fine-grained sand (A-3a), gravel with sand (A-1-b), gravel (A-1-a), and gravel with sand and silt (A-2-4) were also observed. Bedrock was described as non-durable shale interbedded with thin to thick seams of sandstone or siltstone.

### 3.2 CURRENT PROJECT EXPLORATION PROGRAM

Stantec advanced 19 borings to obtain additional geotechnical data for the project. Eleven were for three new companion bridges along US 33, three borings were advanced near the previously observed wet areas planned for fill north of the existing two-lane alignment, and five were advanced in cut slope areas where there were data gaps of bedrock stratigraphy. A summary of these borings is shown in Table 1. Boring locations are shown on the geotechnical profile sheets in Appendix A. The borings were surveyed following the project exploration program.

The borings were advanced in accordance with the ODOT Specifications for Geotechnical Explorations (SGE). The borings were performed with a CME 45 track mounted drill rig using 3¼-inch inside diameter (ID) hollow stem augers to advance the borings through soil. Standard Penetration Test (SPT) sampling was performed at 2.5-foot or continuous intervals until the target depth or bedrock was encountered. The depths and elevations of the SPTs with the corresponding  $N_{60}$ -values are shown on the boring logs in Appendix A and B. The energy ratio (ER) of the automatic hammer and drill rod system was measured to be 93.1 percent on July 5, 2023.

Upon encountering relatively unweathered bedrock in the bridge borings, rock coring was performed using NQ2-size equipment. Recovery, core loss, and rock quality designation (RQD) values were recorded as percentages for each coring run. These values are shown on the boring logs contained in Appendix A and B.

The materials encountered were logged by an engineer or geologist, with attention given to soil type, consistency, and moisture content. The borings were checked for the presence of groundwater during drilling and at its conclusion with the depth of water recorded. The borings were sealed and/or backfilled according to the ODOT SGE.

The soil samples obtained from the borings were returned to a geotechnical laboratory for visual classification and tested for water content. Engineering classification testing was performed on samples reflecting each of the main soil horizons. The engineering classification tests conducted on the samples were sieve and hydrometer analysis (ASTM D422) and Atterberg limits (ASTM D4318). The samples were classified according to the ODOT classification method.

Five Shelby tube sample were extruded in the laboratory, where one unconfined compressive strength of soil (UCS) test (ASTM D2166), four one-dimensional consolidation of soil tests (ASTM D2435) and five engineering classification were completed. Sixteen rock core samples were subjected to unconfined compressive strength of rock core (UCR) testing (ASTM D7012) and five rock samples were subjected to slake durability index (SDI) testing (ASTM D4644). Results of the laboratory testing are included with the boring logs and detailed laboratory reports for unconfined compressive strength testing are provided with the geotechnical profile sheets in Appendix A.

## 4.0 RESULTS OF CURRENT EXPLORATION PROGRAM

### 4.1 BOWMAN'S RUN BRIDGE (MEG-00033-19.462)

Borings B-001-0-23, B-002-0-23, and B-003-0-23 were advanced for the proposed bridge crossing Bowman's Run. Boring B-001-1-24 was advanced to obtain consolidation test samples for soils at the rear abutment. Surficial soils encountered were 3 to 4 inches of topsoil. Moderate and low plasticity fine-grained soils were observed throughout at the site. The soils classified as sandy silt (A-4a) and silt and clay (A-6a). The soils were described as stiff to very stiff, with SPT N<sub>60</sub>-values ranging from 11 to 23 blows per foot with an average of 19 blows per foot. Moisture contents varied from 11 to 16 percent with an average of 14 percent. A bouldery zone was encountered in boring B-002-0-23 from a depth of 1 to 5 feet (Elevation 641.0 to 637.0 feet).

Bedrock was encountered at depths between 1.0 and 7.0 feet (from Elevation 635.0 to 676.3 feet) in the three borings. Rock coring was performed in all three bridge borings. The bedrock obtained from rock coring in B-001-0-23 consisted of sandstone with shale partings. In B-002-0-23, 13.8 feet of sandstone was underlain by claystone until the bottom of boring elevation. The bedrock encountered in B-003-0-23 consisted of 10.3 feet of claystone and shale, underlain by sandstone until the bottom of boring elevation. The sandstone was described as gray to brownish gray, moderately to highly weathered, moderately fractured, coarse grained, and arenaceous. Three UCR tests were completed on samples of sandstone, resulting in compressive strengths ranging from 4,050 to 8,680 pounds per square inch (psi) with an average of 6,116 psi. Claystone was described as reddish brown, moderately to highly weathered, highly to moderately fractured, and argillaceous. The shale was described as tan, highly weathered, and moderately fractured. The shale and claystone were not subjected to UCR testing due to the fragility of the samples.

Groundwater was not encountered in these borings while drilling; however, detection of groundwater may have been obscured by the addition of water during rock coring for the bridge foundation borings. Groundwater level may be present within bedrock. Boring logs and photographs of the rock core are presented with the geotechnical profile sheets in Appendix A.

### 4.2 OLD TOWN CREEK BRIDGE (MEG-00033-23.994)

Borings B-007-0-23, B-008-0-23, and B-009-0-23 were advanced for the proposed new companion bridge crossing Old Town Creek. Boring B-007-1-24 was advanced to obtain consolidation test samples for soils at the rear abutment. Moderate and low plasticity fine-grained overburden soils were observed. The soils classified as sandy silt (A-4a), silt (A-4b), silt and clay (A-6a), silty clay (A-6b), clay (A-7-6), and gravel and stone fragments with sand, silt, and clay (A-2-6). Cohesive soils were described as medium stiff to very stiff, with SPT N<sub>60</sub>-values ranging from 8 to 29 blows per foot with an average of 17 blows per foot. Moisture contents varied from 11 to 28 percent with an average of 17 percent. According to the ODOT Geotechnical Design Manual (GDM), A-2-6 material is considered a "transitional" material that can be described as cohesive or granular depending on laboratory testing. Two samples of A-2-6 soil resulted in plastic limits of 35 and 37 with a plasticity index of 11, which is why the soil was given cohesive strength descriptions.

Bedrock was encountered at depths varying between 5.4 and 25.0 feet (from Elevation 554.9 to 597.8 feet) in the three borings. Rock coring was performed in all three bridge borings. The bedrock obtained from rock coring in B-

008-0-23 consisted of 1.3 feet of claystone underlain by sandstone with shale partings. In B-008-0-23, 2.8 feet of shale was underlain by claystone until the bottom of boring elevation. The bedrock encountered in B-009-0-23 consisted of sandstone with shale partings. The sandstone was described as brown to gray, moderately to highly weathered, moderately to slightly fractured, and coarse grained. Four UCR tests were completed on sandstone samples from these borings, resulting in compressive strengths ranging from 2,706 to 7,610 psi with an average of 5,259 psi. The shale was described as greenish gray, moderately to highly weathered, highly to severely fractured, laminated to thin bedded, and argillaceous. The claystone was described as reddish brown, moderately to highly weathered, highly fractured, laminated, and argillaceous. The shale and claystone were not subjected to UCR testing due to the fragility of the samples.

Groundwater was not encountered in these borings while drilling; however, detection of groundwater may have been obscured by the addition of water during rock coring for the bridge foundation borings. Groundwater level may be present within bedrock. Boring logs and photographs of the rock core are presented with the geotechnical profile sheets in Appendix A.

### **4.3 TRIBUTARY OF OLD TOWN CREEK BRIDGE (MEG-00033-24.307)**

Borings B-010-0-23 and B-011-0-23 were advanced for the new bridge crossing a tributary of Old Town Creek. Boring B-010-24 was advanced to obtain consolidation test samples for soils at the rear abutment. Moderate and low plasticity fine-grained soils were encountered throughout the site. The soils encountered classified as silt and clay (A-6a), clay (A-7-6), and sandy silt (A-4a). The soils were described as medium stiff to hard, with SPT  $N_{60}$ -values ranging from 8 to 38 blows per foot with an average of 18 blows per foot. Moisture contents varied from 12 to 24 percent with an average of 17 percent.

Bedrock was encountered at depths of 25.0 feet (Elevation 569.7 feet) in B-010-0-23 and 3.0 feet (Elevation 603.9 feet) in B-011-0-23. Brown to gray sandstone with dark gray shale partings was encountered in both borings. The sandstone was described as moderately to highly weathered, moderately fractured, coarse grained, micaceous, and arenaceous. Three UCR tests were completed on sandstone samples from these borings, resulting in compressive strengths ranging from 2,437 to 6,820 psi with an average of 3,983 psi. One UCR test was completed on a shale sample, resulting in a compressive strength of 603 psi.

Groundwater was not encountered in these borings while drilling; however, detection of groundwater may have been obscured by the addition of water during rock coring for the bridge foundation borings. Groundwater level may be present within bedrock. Boring logs and photographs of the rock core are presented in with the geotechnical profile sheets Appendix A.

### **4.4 WET AREAS**

Borings B-004-0-23, B-005-0-23, and B-006-0-23 were advanced in the previously observed wet areas planned for fill north of the existing 2-lane alignment. Surficial soils encountered at the site include 2 to 4 inches of topsoil. Moderate and low plasticity fine-grained soils were encountered throughout the sites. The soils encountered classified as silt and clay (A-6a), silty clay (A-6b), clay (A-7-6), and sandy silt (A-4a). The soils were described as medium stiff to very stiff, with SPT  $N_{60}$ -values ranging from 8 to 23 blows per foot with an average of 15 blows per foot. Moisture contents varied from 17 to 32 percent with an average of 21 percent. One sample in Boring B-004-0-23 possessed a moisture

content of 75 percent; however, this boring is located in a wetland area and was not included in the average. One UCS test was performed using the Shelby tube obtained from B-006-0-23, resulting in an unconfined compressive strength of 1.4 tons per square foot (tsf).

Bedrock was encountered at shallow depths (0.3 to 2.5 feet) in B-004-0-23 and B-005-0-23 and at a depth of 15.0 feet in B-006-0-23. Rock coring was not performed in these borings. Groundwater was encountered at a depth of 1.0 feet in Boring B-004-0-23 during drilling. Groundwater was not encountered in other borings while drilling. Boring logs are presented with the geotechnical profile sheets in Appendix A.

## **4.5 CUT SLOPES**

Borings B-006-1-24, B-006-2-24, B-006-3-24, B-012-0-24, and B-013-0-24 were advanced in areas to fill data gaps in bedrock stratigraphy for cut slopes. Surficial soils encountered at the cut slope borings include 1 to 2 inches of topsoil where bulldozing operations did not occur. Moderate and low plasticity soils were encountered in all cut slope borings, classifying as silt and clay (A-6a), silty clay (A-6b), and clay (A-7-6). These soils were described as stiff to hard. The soils were described as stiff to hard, with SPT  $N_{60}$ -values ranging from 23 to 65 blows per foot with an average of 38 blows per foot. Moisture contents varied from 7 to 14 percent with an average of 11 percent.

Bedrock was encountered at depths ranging from 2.0 feet in B-006-2-24 to 19.5 feet in B-013-0-24. Borings typically first encountered red to gray highly weathered shale followed by moderately to highly weathered gray interbedded shale and sandstone, and either slightly weathered grey sandstone or highly weathered reddish gray shale. Five UCR tests were completed on bedrock samples from the cut slope borings. The compressive strength of three shale samples ranged from 2,285 to 6,960 psi, while the strength of two sandstone samples was 3,920 and 4,670 psi. Five SDI tests were completed on each type of rock described. SDI values in weathered shale ranged from 9 to 50 percent, while SDI values in less weathered shale and sandstone ranged from 75 to 97 percent.

Groundwater was not encountered in these borings while drilling; however, detection of groundwater may have been obscured by the addition of water during rock coring for the borings. Groundwater level may be present within bedrock. Boring logs and rock core photographs for the cut slope borings are provided in Appendix B.

## 5.0 ANALYSES AND RECOMMENDATIONS

### 5.1 GENERAL

The recommendations that follow are based on the information discussed in this report and the interpretation of the subsurface conditions documented in historic drilling programs and from those encountered at the site during our fieldwork. If future design changes are made, Stantec should be notified so that such changes can be reviewed, and the recommendations amended as necessary.

These conclusions and recommendations are based on data and subsurface conditions from historic drilling programs and the borings advanced during this exploration using the degree of care and skill ordinarily exercised under similar circumstances by competent members of the engineering profession. No warranties can be made regarding the continuity of conditions.

It is recommended that the project specifications refer to the Ohio Department of Transportation Construction and Materials Specifications (CMS), current edition. The use of special notes referring to the CMS should be included as necessary in relating the construction documents to the specific conditions within the project limits.

### 5.2.2 Bridge Foundations

Bridge abutments and piers may be supported by drilled shafts, steel H-piles driven to refusal on bedrock, or prebored H-piles. The structural engineer for this project indicated the preferred foundation type would be drilled shafts because drilled shafts were successfully used for the existing bridges. Drilled shaft capacity calculation results for each bridge are provided in the following sections. The recommended side and tip resistances for drilled shafts were estimated following guidelines in the AASHTO LRFD Bridge Design Specifications 9<sup>th</sup> Edition Article 10.8.3.5 using the compressive strength of the bedrock. Where interbedded layers of soft and hard bedrock were observed, weighted averages of compressive strengths were used. A typical compressive strength of claystone was used because no samples were able to be tested due to the fragile nature of the claystone at the site. A side resistance factor of 0.55 and tip resistance factor of 0.50 are recommended based on Table 305-1 in the 2020 ODOT BDM for drilled shafts bearing on rock.

For the drilled shaft resistance calculations, it was assumed that two feet of the 10-foot rock socket will be in severely to highly weathered bedrock that was augured through during the exploration. The remaining eight feet will be in cored bedrock, considered to be “competent” rock. The side resistance was determined by using a weighted average of the rock strengths in the first eight feet of competent rock. The tip resistance was determined by using a weighted average of the rock strengths below the assumed rock socket to the terminus of each boring. Supporting calculations for each bridge are provided in Appendix D.

The shaft resistance provided by non-scour resistant bedrock should be neglected in the scour zone as recommended in Section 305.4.1.1 of the 2020 ODOT BDM. At a minimum, shaft resistance should be neglected for the top 2 feet of bedrock. Drilled shafts socketed into non-scour resistant bedrock should be extended a minimum of 10 feet below the controlling scour elevation in the bedrock. The recommended side and tip resistances assume a minimum rock socket length of 1.5 times the rock socket diameter as stated in section 305.4.2 of the 2020 ODOT BDM. Side resistance should be neglected for rock sockets with less than 1.5 times the rock socket diameter. When determining the load capacity of the bedrock below each bridge, consider either the side or tip resistance according to GDM Section 1306.1.2. If both are used, guidelines provided in Section 1306.3.2 of the GDM should be followed.

**5.2.2.1 Bowman’s Run Bridge (MEG-00033-19.462)**

The most common rock type at the two-span bridge crossing Bowman’s Run is the sandstone bedrock encountered in all three borings for the bridge. A typical rock compression strength of 6,116 psi was selected for drilled shaft capacity calculations based on the rock compression test results performed in borings B-001-0-23 and B-003-0-23. Shale and claystone bedrock were also encountered in the borings. A typical rock compression strength of 600 psi was assigned to shale from the sample tested in B-010-0-23. A value of 250 psi was selected for claystone bedrock based on testing from other projects and the bedrock conditions observed. Recommended nominal and factored side and tip resistances for each substructure unit are provided in Table 8 through Table 10.

**5.2.2.2 Old Town Creek Bridge (MEG-00033-23.994)**

The most common rock type at the two-span bridge crossing Old Town Creek is the sandstone bedrock encountered in all three borings for the bridge. A typical rock compression strength of 5,259 psi was selected for drilled shaft capacity calculations based on the rock compression test results performed in borings B-007-0-23 and B-009-0-23.

Shale and claystone bedrock were also encountered in the borings. A typical rock compression strength of 600 psi was assigned to shale from the sample tested in B-010-0-23. A value of 250 psi was selected for claystone bedrock based on testing from other projects and the bedrock conditions observed. ### 5.2.2.3 Tributary of Old Town Creek Bridge (MEG-00033-24.307)

The most common rock type at the single-span bridge crossing a tributary of Old Town Creek is the sandstone bedrock encountered in all three borings for the bridge. A typical rock compression strength of 3,983 psi was selected for drilled shaft capacity calculations based on the rock compression test results performed in borings B-010-0-23 and B-011-0-23. Shale bedrock was also encountered in the borings. A typical rock compression strength of 600 psi was assigned to shale from the sample tested in B-010-0-23. ### 5.2.3 Seismic Site Classification

A site-specific seismic classification was developed using the SPT N-values recorded during the field exploration program at each bridge location. The following sections discuss the results of each analysis. Seismic site classification is determined according to the ODOT BDM and 9<sup>th</sup> Edition AASHTO LRFD Bridge Design Specification (2020). N-values to a depth of 100 feet are used to determine seismic site classification. If bedrock was encountered before a depth of 100 feet, an N-value of 100 is assigned from the bedrock depth to 100 feet. Calculations for each site classification are provided in Appendix E.

#### 5.2.3.1 Bowman’s Run Bridge (MEG-00033-19.462)

An average N-value of 80.1 was calculated at the bridge location based upon the two abutment borings and one pier boring advanced for this project. Per the current AASHTO LRFD Bridge Design Specifications and an average N-value of 80.1, the site classified as Seismic Site Class C.

#### 5.2.3.2 Old Town Creek Bridge (MEG-00033-23.994)

An average N-value of 44.8 was calculated at the bridge location based upon the two abutment borings and one pier boring advanced for this project. Per the current AASHTO LRFD Bridge Design Specifications and an average N-value of 44.8, the site classified as Seismic Site Class D.

#### 5.2.3.3 Tributary of Old Town Creek Bridge (MEG-00033-24.307)

An average N-value of 55.3 was calculated at the bridge location based upon the two abutment borings advanced for this project. Per the current AASHTO LRFD Bridge Design Specifications and an average N-value of 55.3, the site classified as Seismic Site Class C.

### 5.2.4 Lateral Load Analyses

A lateral capacity analysis was performed for the abutment and pier piles at each bridge using the computer program LPILE v 2022. The lateral loads were provided by the structural designer and were computed from the bridge loading and the lateral earth pressures on the back of the abutment wall above the driven piles. Detailed results of the LPILE analysis are shown in Appendix F. Drilled shafts were modeled for the abutments and piers. Group effects were taken into account by applying a P-multiplier as specified in the *AASHTO LRFD Bridge Design Specifications* Section 10.7.2.4. The methodology for applying the multipliers is shown in Appendix F.

Multiple loading cases were analyzed for each substructure. Each case was analyzed with service limit state loading and strength limit state loading, as provided by the structural designer. The service limit state cases are used to determine the maximum deflection of the piles, while the strength limit state cases provide shear and bending

moments for structural capacity analysis. Shear and moment loading provided by the structural engineer were input into each load case at each substructure unit. Maximum results for each bridge substructure are summarized in Table 16, Table 17, and Table 18.

**Table 16. Lateral Load Analysis Results; Bowman’s Run Bridge**

Bridge Substructure	Maximum Deflection (in)	Maximum Shear (kips)	Maximum Moment (kip-ft)
Rear Abutment	0.12	119.4	381.7

### 5.2.5 Approach Embankments

The need for slope stability and settlement calculations were evaluated at the bridge approach embankments. Maximum approach embankment height required to reach planned roadway elevation is expected to be less than 20 feet (19 feet for Bowman’s Run Bridge, 19 feet for Old Town Creek Bridge, and 18 feet for Tributary of Old Town Creek Bridge). Slopes of 2H:1V are recommended for embankments of this height. Settlement analyses are to be considered for the rear abutment of all three bridges. Analyses for the forward abutments are not required due to the need of rock cuts to reach the foundation elevation for each bridge.

According to the ODOT GDM Section 1303.2.1, settlement for foundations on cohesive soils may be assumed to be negligible if the Service Limit State bearing stress over the effective area is less than 50 percent of the undrained shear strength of the foundation soil. The bearing stress from the embankment onto the foundation soils was assumed to be the unit weight of unknown embankment fill (125 pcf) times the maximum height of the embankment. After comparing undrained shear strengths developed using relationships provided in Section 404 of the ODOT GDM

with the bearing stresses at each embankment location, it was determined that settlement analyses would be needed at all three locations.

Settlement analyses using Settle3D modelling software were performed for the rear approach embankment at each bridge. Subsurface conditions were based on the results of boring near this structure and soil parameters were based on consolidation tests performed in offset borings. Laboratory test results and settlement parameter estimations are provided in Appendix G.

Due to the cohesive nature of the soil at the site, no immediate settlement was predicted. Results from the Settle3D analyses are provided in Appendix G. The results of the consolidation settlement predictions are summarized in Table 19.

**Table 19. Summary of Settlement Analyses at Rear Approach and Abutment**

<b>Rear Approach Abutment</b>	<b>Estimated Consolidation Settlement (inches)</b>	<b>Recommended Waiting Period Before Construction of Drilled Shafts (Days)</b>
Bowman’s Run Bridge (MEG-00033-19.462)	3.4	94
Old Town Creek Bridge (MEG-00033-23.994)	5.4	35
Tributary of Old Town Creek Bridge (MEG-00033-24.307)	13.2	62

Predicted settlement at each rear approach is greater than the 0.4 inches required to mitigate down drag loading on the drilled shafts. Table 19 also provides the recommended waiting period at for each bridge abutment prior to drilled shaft construction to allow settlement of the foundation soils to occur and reduce down drag loading. To monitor the consolidation, settlement platforms are recommended. The reading of these platforms will allow construction to proceed once the Engineer has determined that sufficient settlement has occurred. Two platforms are recommended at each rear approach abutment at Stations 974+90, 1,214+00, and 1,230+50, one just beyond the left shoulder and one just beyond the right shoulder.

### **5.2.6 Lateral Earth Pressure**

Temporary sheeting and shoring systems should be designed to withstand the development of lateral earth pressures and hydrostatic pressures. The magnitude of such pressures varies based on soil type, permissible wall movement and configuration of backfill. Table 20 provides the recommended lateral earth pressure parameters for on-site cohesive soil and select granular backfill. The friction angle of on-site soil was determined using blow count relationships. Assumed material properties for embankment fill are outlined in Table 500-2 of the GDM. Material properties for select granular backfill are provided in the ODOT Construction and Materials Specifications (CMS).

**Table 20. Lateral Earth Pressure Parameters**

Soil Parameter	Soil at Project Site	ODOT Assumed for Unknown Soil	Granular Backfill
<b>Drained Friction Angle (degrees)</b>	24	26	32
<b>Unit Weight (pcf)</b>	Moist	122	120
	Buoyant	60	73
<b>Earth Pressure Coefficient</b>	Active Case ( $K_A$ )	0.37	0.28
	Passive Case ( $K_P$ )	4.01	7.8
	At-Rest Case ( $K_0$ )	0.59	0.47
<b>Equivalent Fluid Unit Weights (pcf)</b>	Active Case	45	34
	Passive Case	489	936
	At-Rest Case	72	56

To reduce lateral earth pressures applied to the retaining structures due to hydrostatic buildup, free drainage should be provided in accordance with ODOT CMS Item 518. Placement of the granular backfill should be in accordance with ODOT CMS Item 518.05 “Porous Backfill”. Positive drainage of the granular backfill using weepholes or pipe drains is necessary to minimize the hydrostatic pressures against the structures. Providing positive drainage from the backfill will allow the use of the design parameters associated with the “drained” condition. If selected walls are capable of deflecting a distance of approximately 0.1 percent of the wall height, then an “active” condition could be used for design. If not, the “at-rest” condition should be used for design.

Backfill comprised of cohesive soils and/or granular soils with significant clay content may result in high magnitudes of lateral loads due to creep and swelling pressures. These materials are not recommended for use as backfill behind permanent structures. It is recommended that a backfill material comprised of free-draining granular material, such as the material specified under ODOT CMS Item 518.03, be used. The backfill material should be coarse angular gravel with a gradation equivalent to No. 57 aggregate, as specified under ODOT CMS Item 703, Table 703.01-1.

Backfill should be compacted in accordance with ODOT CMS Item 203.07 “Compaction and Moisture Requirements”. Overcompaction in areas directly behind structures should be avoided as this can cause damage to the structures. Appropriate equipment should be used to obtain the required compaction without causing damage.

## 5.3 ROADWAY RECOMMENDATIONS

### 5.3.1 Cut Slopes

Guidelines outlined in ODOT’s GDM section 1000, results of the UCR testing, historical exploration data, existing natural slopes, and experience on similar projects were used to establish recommendations for cut slope configurations within various soil and bedrock types.

Cuts will be necessary left of centerline along the alignment to allow for the widening of US 33 to four lanes. The cut slopes used for the two-lane highway were used as a general guide for the cut slopes for the widening. Where sandstone is expected, the slopes were designed with a 1:1 grade. Where shale, claystone, or mudstone is anticipated, the slopes were designed with a 2:1 grade. Intermediate benches were positioned atop where poor bedrock is anticipated, where construction limits allowed, to prevent undermining, and to provide a reduction to stormwater drainage velocity down the slope. The design of the catchment for the widening meets the intent of the guidelines presented in the ODOT GDM.

Where 1:1 cut slopes are planned on the lower slopes that are at least 10 feet tall, rockfall catchment should be provided in accordance with Table 1000-4 of the ODOT GDM. It is recommended that the planned catchment ditches consist of a combination of flat ditch (typically 10 feet wide) and foreslope catchment on a 4:1 slope that, combined with the flat ditch, provide a total catchment width of 20 feet. This is applicable from Station 964+50 to 966+00, 968+00 to 973+00, and 978+50 to 983+50, as well as from Station 1217+00 to 1218+00.

Along the current two-lane alignment, there are four Tier 2 Rockfall Sites within the project limits. These sites were reviewed during the field review and photos were viewed on the ODOT TIMS website. Table 21 provides a description of the conditions at the sites and the proposed rock cut in the area of that site.

**Table 21. Rock Cut Slope Conditions and Recommendations**

Tier 2 Site Straight Line Mileage and Approximate Project Stationing	Description of Cut Slope Condition	Planned Cut Slope for Widening
19.229 / 967+78	Degrading sandstone at base of cut and eroding shale at top	1:1 within the sandstone at the base and 2:1 in shale at top
24.076 / 1223+70	Slip at upper portion of cut near 2nd bench, erosion gullies in shale throughout	2:1 with intermediate bench(es)
24.321 / 1236+64	Lower existing 1:1 looks to be in shale and not performing well, erosion in shale on upper portion	Lower 1:1 removed, 2:1 with intermediate bench(es)
24.949 / 1269+80	Slip on lower slope, erosion gullies throughout	2:1 with intermediate bench(es)

In summary, cutting further into the slopes should improve the rock quality by exposing fresher bedrock and help against rockfall being an issue on the planned slopes. The removal of the lower 1:1 slope near mile marker 24.321 and making the entire cut a 2:1 slope should result in a less rockfall prone slope.

The computer program *RocFall*, Version 6.011, developed by Rocscience Inc. was used to run rockfall simulations for the stations listed in Table 21 using the guidelines suggested by ODOT in Section 503 of the *Rock Slope Design Guide*. To be conservative, strong smooth rock was used to model the outcrop and 500 one-foot spherical rock specimens were used on each exposed slope. For each simulation, energy from 100 percent of the rockfalls was dissipated on either the slope or in the catchment area, with no rockfall specimens entering the roadway. Outputs from the *RocFall* program can be found in Appendix H.

### 5.3.2 Embankment Slopes

Critical embankment cross sections were analyzed for slope stability using the program Slope/W from GeoStudio, Inc. A minimum of one section was chosen from each embankment along the project length, varying in slope from 2:1 to 3:1, as shown on the design cross sections. Short-term analyses, using total stress shear strength parameters for foundations and embankment materials, simulate conditions that will exist during embankment construction and immediately following completion of the embankment. Long-term analyses, using effective-stress shear strength parameters, simulate conditions that will exist long after the embankment is constructed and excess pore pressures within the foundation materials have dissipated. The computed factor of safety was compared to ODOT’s published minimum factor of safety for embankments, as shown in Table 22.

**Table 22. ODOT Minimum Factors of Safety for Slope Stability**

Embankment Scenario	Short-Term	Long-Term
Roadway Embankment	1.3	1.3
Embankments Supporting Structures	1.3	1.5

The shear strength parameters for the foundation soils were derived from soil classifications and laboratory testing of the historic and current explorations, SPT values, and associated published correlations of such data. The proposed embankment material is assumed to consist mostly of cut material along the project alignment, which is a combination of mostly shale bedrock and, to a lesser degree, cohesionless and cohesive soils. Table 23 shows the selected shear strength values of the embankment material used in the analyses. These values closely reflect the parameters used during the evaluation of the existing slopes in the historic geotechnical reports and analysis.

**Table 23. Embankment Material Shear Strength Parameters**

Parameter	Total Stress	Effective Stress
c or c' (psf)	1,500	200
$\Phi$ or $\Phi'$ (deg)	0	20
$\gamma$ (pcf)	125	125

It was determined that factors of safety for 2H:1V slopes (or steeper) of heights greater than 25 feet will have lower than the ODOT recommended values for short-term and/or long-term conditions when using the embankment strengths shown in Table 22. These sections could be constructed using reinforced soil slopes (RSS) to achieve acceptable factors of safety. Results of the reinforced soil slope analyses are summarized in Section 5.3.3 and presented in Appendix J.

Alternatively, slope stability analyses were performed at two cross sections with 1.5H:1V or 2H:1V slopes of heights greater than 25 feet, but with soil strengths for the new embankment chosen from the values in Table 500-2 of the GDM, which assume stronger shear strength for proposed embankment material than shown in Table 22. It was assumed that the proposed embankment would consist of A-6b (silty clay) soil when the excavated shale material is broken down. The drained shear strength derived from GDM Table 500-2 were a cohesion of 250 psf, and friction angle of 28 degrees. The corresponding undrained shear strength assumed from the GDM was 2,500 psf cohesion

with a friction angle of zero. The factors of safety for these two cross sections with increased soil strength yielded adequate values for both short- and long-term conditions. A comparison of these factors of safety is presented in Table 24.

**Table 24. Embankment Stability Results of 2:1 Slopes greater than 25 feet in Height**

Station	Slope	Proposed Embankment Strengths	Applies to Station		Short Term FS	Long Term FS
			From	To		
1019+50	1.5H:1V	Report Table 22	1016+00	1020+00	1.5	1.0
1019+50	1.5H:1V	GDM Table 500-2	1016+00	1020+00	1.6	1.3
1022+00	2H:1V	Report Table 22	1020+00	1025+50	1.6	1.2
1022+00	2H:1V	GDM Table 500-2	1020+00	1025+50	1.8	1.6

Based on the results of this analysis and comparison, it would be acceptable that the 2H:1V slope at Station 1019+50 be unreinforced. It is not recommended that the 1.5H:1V slope at Station 1019+50 be unreinforced due to past experience showing that slopes steeper than 2H:1V have long term stability issues. If the slope configuration at Station 1019+50 can be adjusted to have a 2H:1V slope, the factors of safety for slope stability for an unreinforced slope would be adequate using the embankment parameters from GDM Table 500-2.

Table 25 summarizes the results of the slope stability analyses for the remaining 2:1 slopes of heights less than 25 feet, as well as 3:1 slopes, along with the stationing ranges that each cross section represents. The Slope/W analysis files showing the cross sections, shear strength parameters, and calculated factors of safety can be found in Appendix I.

**Table 25. Embankment Stability Results**

Station	Slope (H:V)	Applies to Station		Short Term FS	Long Term FS
		From	To		
1053+00	2:1	1053+00	1055+00	3.4	1.5
1076+50	2:1	1076+50	1077+50	3.7	1.6
1155+00	3:1	1153+00	1156+00	2.2	1.6
1178+50	3:1	1177+00	1180+00	2.1	1.6
1230+50	2:1	1230+00	1230+50	2.7	1.4
1341+50	3:1	1337+00	1346+50	1.5	1.7
1353+00	3:1	1350+00	1353+50	1.3	1.7
1367+50	3:1	1367+00	1370+00	1.1	1.6

The slope stability results indicate that the predicted short-term factor of safety at station 1367+50 does not meet the minimum factor of safety required by ODOT as shown in Table 22. Where the factor of safety is lower than the targeted value, remedial methods should be utilized for the embankment construction, such as a controlled rate of fill placement. Settlement versus time relationships were used to estimate the permissible construction rates for this cross section using a control rate of fill. This rate was calculated assuming the gain in shear strength for foundation soil under imposed loads should be proportional to the percent consolidation. A summary of the results is shown in Table 26 and the calculations are presented in Appendix I.

**Table 26. Summary of Permissible Construction Rates**

Station Analyzed	Maximum Embankment Elevation using Normal Construction Rates (feet)	Permissible Construction Rate (feet/week)	Approximate Station Interval for Rate Construction
1367+50	633	3.4	1367+00 to 1369+50

Settlement platforms and piezometers should be installed to monitor settlement and pore water pressures of the foundation soils during construction using controlled rate of fill methods. If excess pore water pressure is observed during the construction, appropriate remedial construction techniques should then be initiated to maintain embankment stability.

It is recommended that the rate of embankment construction be controlled to maintain adequate short term slope stability of the roadway embankments, as summarized in Table 27. Normal construction rates can be used up to the elevations given, then a controlled rate of fill be used above that elevation to final grade. A piezometer is recommended to be installed prior to embankment construction to monitor the pore water pressures of the foundation soils. Based upon the piezometer readings, the construction of the embankments may be restricted and, if necessary, halted until excess pore pressures have dissipated. The following recommended piezometer locations are preliminary and may be modified prior to construction. The number of piezometers installed at each location and the elevations at which they are installed are dependent upon the subsurface conditions present. A minimum of one piezometer should be installed for each compressible horizon at the recommended location. Additional piezometers should be installed in locations where there may be a concern for foundation instability beneath the embankment fill at the direction of the Engineer.

**Table 27. Piezometer Installation Locations**

Station	Offset (feet)	Elevation of Piezometer Tip (feet)
1367+50	140 Left	575

Review of existing ground on surveyed cross sections show hummocky ground, indicative of a preexisting or current landslide, was evident upslope from the alignment near Station 1030+00. A back calculation was performed to determine the in-situ soil strength corresponding to a factor of safety for slope stability of 1.0, given the existing geography and topography. Once determined, those soil strengths were used in conjunction with an excavate and replace approach within the existing right-of-way, replacing the existing material with No. 2 stone. The resulting long-term factor of safety is 1.7. Refer to the output of the stability analysis in Appendix I.

It is Stantec's understanding that the roadway embankments for this project will be constructed using material from cut areas. A review of the subsurface conditions encountered within the cut intervals indicates that the excavated material will consist primarily of non-durable shale and claystone, along with durable and non-durable sandstone. Durable sandstone should be utilized at the bottoms of fill areas to provide a stable base for embankment construction.

Any saturated, soft, and unstable areas encountered within embankment foundation limits and/or other areas as specified by the Engineer should be stabilized using broken durable sandstone from cut areas in accordance with

CMS 203.06.C. A minimum three-foot working platform should be constructed in such areas. The materials should be placed as directed by the Engineer based on site and climatic conditions during construction.

Special benching should be constructed for the embankments for the stations listed below to aid in long term stability. The benches should be constructed one at a time beginning with the lowest bench. The Stantec geotechnical engineering team designed the special benching shown on the construction plan cross sections where deemed necessary.

### 5.3.3 Embankment Settlement

A settlement analysis using Settle3D modelling software was performed on a typical embankment cross-section representing conditions from Station 1337+00 to 1370+00 where embankment heights of up to 30 feet are planned to be placed upon existing embankment material and silty soil foundation deposits exceeding 40 feet in depth. Subsurface conditions were based on the results of historic borings completed near Station 1367+50 and soil consolidation parameters were based on consolidation tests performed during the current exploration. Laboratory test results and settlement parameter estimations are provided in Appendix G. Due to the cohesive nature of the soil at the site, immediate settlement was negligible. The analysis was performed assuming that the existing embankment placed in the early 2000s caused a certain amount of settlement and the planned embankment would cause additional consolidation to occur. According to the settlement analysis, approximately 4 inches of settlement is expected after constructing and keying in the widened embankment to the existing embankment. Results from the Settle3D analyses are provided in Appendix I.

Because the analysis predicts that the settlement caused by embankment construction from Station 1337+00 to 1370+00 is expected to be greater than 3 inches, corrective actions are required by the GDM. Therefore, the settlement analysis described above estimated the time to get to within 3 inches of the predicted total settlement. Based on the result of the analysis, a waiting period of 35 days is recommended before pavement construction from Station 1337+00 to 1370+00. To monitor the consolidation, settlement platforms are recommended. The reading of these platforms will allow construction to proceed once the Engineer has determined that sufficient settlement has occurred. Settlement platforms are recommended at Station 1341+00, 1353+00, and 1367+50 at offsets of 70 feet left of center.

### 5.3.4 Reinforced Soil Slopes

Where it is not feasible to use 3H:1V slopes for embankments greater than 25 feet tall, geogrid reinforced soil slopes could be used to achieve acceptable factors of safety (although the analysis explained in Section 5.3.2 showed that 2H:1V slopes are acceptable using GDM-recommended shear strength parameters for proposed embankments). The reinforced slopes were designed as 2H:1V slopes with the necessary geogrid reinforcement to achieve slope stability factors of safety required by ODOT for embankments. The 2H:1V slopes are being used for areas where right-of-way restrictions prohibit the use of shallower slopes.

The computer program ReSSA was used for the design of the reinforced soil slopes. The slopes were analyzed for short-term and long-term conditions. Simplified geometry and foundation soil characterization were used because of the software limitations. The Comprehensive Bishop Method was used for global slope stability estimations. A traffic surcharge load of 250 pounds per square foot was used at the crest of the slope. The guidelines in the ODOT

Supplemental Specification 863 titled “Reinforced Soil Slopes” were used for selection of geogrid tensile strengths and resistance factors. The results of the analyses are summarized in Table 28 and are included in Appendix J.

**Table 28. Reinforced Soil Slope Stability Results for 2H:1V Slopes**

Station	Applies to Station		Short Term FS	Long Term FS
	From	To		
1019+50	1019+50	1020+00	1.5	1.3
1022+00	1020+50	1026+00	1.5	1.3

Primary geogrid reinforcement should be used to support the embankment on the steepened slope, and secondary reinforcement near the face of the slope should be used to protect against sloughing and shallow instability.

### 5.3.5 Subgrade Stabilization

The ODOT Geotechnical Design Manual (GDM) outlines the procedure for estimating the methods and limits of subgrade treatment that will be required to stabilize pavement subgrade prior to construction of the pavement section. The procedure is based on the results of a series of Dynamic Cone Penetrometer (DCP) borings, SPT borings, field testing, and laboratory testing.

A subgrade analysis was performed in accordance with ODOT GDM. Forty DCP tests were conducted along the alignment in April 2023. Thirteen of these locations were performed at stations where mechanical classification of the subgrade soil was completed. The DCP tests and mechanical classification results are shown on the geotechnical profile sheets in Appendix A. To perform the subgrade stability analysis, the results of the DCP tests were correlated to SPT blow counts (N-value) using the procedure outlined in *Validation of Correlations Between a Number of Penetration Tests and In Situ California Bearing Ratio Tests* (Transportation Research Record 1219, 1989, pp 56-67). The number of blows to penetrate successive two-inch increments in the subgrade soil was used to determine the DCP Index, which was correlated to a California Bearing Ratio (CBR) percentage. The CBR percentage was used to determine the SPT (mm/blow) from Equation 3 or Figure 1 of the TRR paper. The SPT value was converted to the imperial unit system and the value used to determine the number of blows per foot. These values were used as inputs in the Subgrade Analysis spreadsheet for the Standard  $N_{60}$  values to determine areas of unstable soil that would need to be remedied. Refer to the Subgrade Analysis spreadsheet in Appendix K. An average  $N_{60L}$  of 19 was calculated from the data obtained from the borings. A design CBR of 7 was estimated based on the subgrade analysis.

Unsuitable or unstable soils were present along the alignment, but in only 27 percent (4 of 13) of the subgrade borings, thus not necessitating global remediation. The DCP testing indicates that subgrade stabilization may be necessary from approximately Station 1305+00 to 1343+00, but only where less than 3 feet of cut or fill is planned. As such, 12 inches of subgrade stabilization should be assumed for about 10 percent of this station range that consists of several deep cuts and fills not requiring stabilization.

Excavation for subgrade stabilization should extend 12 inches beyond the edge of the surface of the pavement, and ODOT CMS Item 204 Geotextile Fabric should be placed underneath the selected granular fill material. Select fill should consist of Type B or C granular material.

## REPORT OF ROADWAY EXPLORATION (FINAL) – MEG-33-19.11

Where bedrock is exposed at the subgrade elevation, an undercut and replacement operation should be performed so that a more consistent and less rigid material underlies the pavement section. In these areas, rock, shale, or coal encountered in the subgrade should be excavated to 6 inches below the final subgrade elevation. It should be ensured that the excavated surface be shaped to drain and have a uniform surface that cannot trap water. The excavation should extend for a width of 1 foot beyond the roadway shoulders. The excavation should be replaced to the subgrade profile with suitable material conforming to ODOT CMS 204.02 Granular Material Type B, following the gradation of 703.17, and compacted according to 204.03. From review of the cross sections, bedrock undercutting would be needed within these approximate station ranges:

- 963+25 to 974+25
- 977+75 to 988+50
- 1009+75 to 1010+25

- 1118+75 to 1120+75
- 1130+25 to 1136+25
- 1141+25 to 1143+75
- 1160+00 to 1168+25

GROUNDWATER WAS NOT ENCOUNTERED IN THESE BORINGS WHILE DRILLING; HOWEVER, DETECTION OF GROUNDWATER MAY HAVE BEEN OBSCURED BY THE ADDITION OF WATER DURING ROCK CORING FOR THE BRIDGE FOUNDATION BORINGS. GROUNDWATER LEVEL MAY BE PRESENT WITHIN BEDROCK.

**WET AREAS**

BORINGS B-004-0-23, B-005-0-23, AND B-006-0-23 WERE ADVANCED IN THE PREVIOUSLY OBSERVED WET AREAS PLANNED FOR FILL NORTH OF THE EXISTING 2-LANE ALIGNMENT. SURFICIAL SOILS ENCOUNTERED AT THE SITE INCLUDE 2 TO 4 INCHES OF TOPSOIL. MODERATE AND LOW PLASTICITY FINE-GRAINED SOILS WERE ENCOUNTERED THROUGHOUT THE SITES. THE SOILS ENCOUNTERED CLASSIFIED AS SILT AND CLAY (A-6A), SILTY CLAY (A-6B), CLAY (A-7-6), AND SANDY SILT (A-4A). THE SOILS WERE DESCRIBED AS MEDIUM STIFF TO VERY STIFF.

BEDROCK WAS ENCOUNTERED AT SHALLOW DEPTHS (0.3 TO 2.5 FEET) IN B-004-0-23 AND B-005-0-23. BEDROCK WAS ENCOUNTERED AT A DEPTH OF 15.0 FEET IN B-006-0-23. ROCK CORING WAS NOT PERFORMED IN THESE BORINGS. GROUNDWATER WAS ENCOUNTERED AT A DEPTH OF 1.0 FEET IN BORING B-004-0-23 DURING DRILLING.

GROUNDWATER WAS NOT ENCOUNTERED IN OTHER BORINGS WHILE DRILLING.

**CUT SLOPES**

BORINGS B-006-1-24, B-006-2-24, B-006-3-24, B-012-0-24, AND B-013-0-24 WERE ADVANCED IN AREAS WHERE LITTLE PROFILE INFORMATION WAS AVAILABLE FOR CUT SLOPES. SURFICIAL SOILS ENCOUNTERED AT THE CUT SLOPE BORINGS INCLUDE 1 TO 2 INCHES OF TOPSOIL WHERE BULLDOZING OPERATIONS DID NOT OCCUR. MODERATE AND LOW PLASTICITY SOILS WERE ENCOUNTERED IN ALL CUT SLOPE BORINGS, CLASSIFYING AS SILT AND CLAY (A-6A), SILTY CLAY (A-6B), AND CLAY (A-7-6). THESE SOILS WERE DESCRIBED AS STIFF TO HARD.

BEDROCK WAS ENCOUNTERED AT DEPTHS RANGING FROM 2.0 FEET IN B-006-2-24 TO 19.5 FEET IN B-013-0-24. BORINGS TYPICALLY FIRST ENCOUNTERED RED TO GRAY HIGHLY WEATHERED SHALE FOLLOWED BY MODERATELY TO HIGHLY WEATHERED GRAY INTERBEDDED SHALE AND SANDSTONE, AND EITHER SLIGHTLY WEATHERED GREY SANDSTONE OR HIGHLY WEATHERED REDDISH GRAY SHALE.

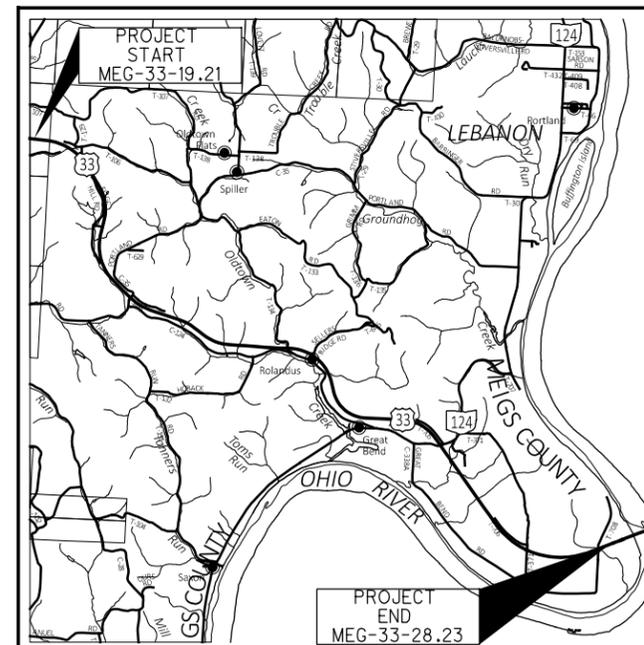

GROUNDWATER WAS NOT ENCOUNTERED IN THESE BORINGS WHILE DRILLING; HOWEVER, DETECTION OF GROUNDWATER MAY HAVE BEEN OBSCURED BY THE ADDITION OF WATER DURING ROCK CORING FOR THE BRIDGE FOUNDATION BORINGS. GROUNDWATER LEVEL MAY BE PRESENT WITHIN BEDROCK.

### Critical Shear Stress

$$\tau_c = \rho \left( \frac{1000 K^{0.75}}{7.853 \rho} \right)^{2/3}$$

ODOT GDM Section 1302.1.3

where:

- $\tau_c$  = Critical shear stress (Pa)
- $\rho$  = Mass density of water (1000 kg/m<sup>3</sup>)
- K = Erodibility Index (dim.)

$$K = (M_s)(K_b)(K_d)(J_s)$$

HEC 18 Equation 4.17

where:

- K = Erodibility Index
- $M_s$  = Intact rock mass strength parameter
- $K_b$  = Block size parameter
- $K_d$  = Shear strength parameter
- $J_s$  = Relative orientation parameter

$M_s$	=	35	(see determination below)
$K_b$	=	17.20	(see determination below)
$K_d$	=	0.25	(see determination below)
$J_s$	=	1.05	(see determination below)
K	=	158.03	
$\tau_c$ , Pa	=	3181.8	
$\tau_c$ , psf	=	66.47	

### Erosion Category (EC)

$S_v$ , mm	=	160	(average vertical spacing between horizontal discontinuities)
EC	=	4.367	(note if $S_v < 0.2$ mm, 0.2 mm is used in the EC calculation)

## J<sub>s</sub> Determination

1.05 J<sub>s</sub> (HEC 18 Table 4.26)

From HEC-18:

Relative orientation, in the case of rock, is a function of the relative shape of the rock and its dip and dip direction relative to the direction of flow. The relative orientation parameter J<sub>s</sub> represents the relative ability of earth material to resist erosion due to the structure of the ground. This parameter is a function of the dip and dip direction of the least favorable discontinuity (most easily eroded) in the rock with respect to the direction of flow, and the shape of the material units. These two variables (orientation and shape) affect the ease by which the stream can penetrate the ground and dislodge individual material units.

Conceptually, the function of the relative orientation parameter J<sub>s</sub> incorporating shape and orientation is as follows. If rock is dipped against the direction flow, it will be more difficult to scour the rock than when it is dipped in the direction of flow. When it is dipped in the direction of flow, it is easier for the flow to lift the rock, penetrate underneath and remove it. Rock that is dipped against the direction of flow will be more difficult to dislodge. The shape of the rock, represented by the length to width ratio *r*, impacts the erodibility of rock in the following manner. Elongated rock will be more difficult to remove than equi-sided blocks of rock. Therefore, large ratios of *r* represent rock that is more difficult to remove because it represents elongated rock shapes. Values of the relative orientation parameter J<sub>s</sub> are provided in Table 4.26.

## J<sub>s</sub> Determination

1.05 J<sub>s</sub> (HEC 18 Table 4.26)

From HEC-18:

Relative orientation, in the case of rock, is a function of the relative shape of the rock and its dip and dip direction relative to the direction of flow. The relative orientation parameter J<sub>s</sub> represents the relative ability of earth material to resist erosion due to the structure of the ground. This parameter is a function of the dip and dip direction of the least favorable discontinuity (most easily eroded) in the rock with respect to the direction of flow, and the shape of the material units. These two variables (orientation and shape) affect the ease by which the stream can penetrate the ground and dislodge individual material units.

Conceptually, the function of the relative orientation parameter J<sub>s</sub> incorporating shape and orientation is as follows. If rock is dipped against the direction flow, it will be more difficult to scour the rock than when it is dipped in the direction of flow. When it is dipped in the direction of flow, it is easier for the flow to lift the rock, penetrate underneath and remove it. Rock that is dipped against the direction of flow will be more difficult to dislodge. The shape of the rock, represented by the length to width ratio *r*, impacts the erodibility of rock in the following manner. Elongated rock will be more difficult to remove than equi-sided blocks of rock. Therefore, large ratios of *r* represent rock that is more difficult to remove because it represents elongated rock shapes. Values of the relative orientation parameter J<sub>s</sub> are provided in Table 4.26.

## J<sub>s</sub> Determination

1.05 J<sub>s</sub> (HEC 18 Table 4.26)

From HEC-18:

Relative orientation, in the case of rock, is a function of the relative shape of the rock and its dip and dip direction relative to the direction of flow. The relative orientation parameter J<sub>s</sub> represents the relative ability of earth material to resist erosion due to the structure of the ground. This parameter is a function of the dip and dip direction of the least favorable discontinuity (most easily eroded) in the rock with respect to the direction of flow, and the shape of the material units. These two variables (orientation and shape) affect the ease by which the stream can penetrate the ground and dislodge individual material units.

Conceptually, the function of the relative orientation parameter J<sub>s</sub> incorporating shape and orientation is as follows. If rock is dipped against the direction flow, it will be more difficult to scour the rock than when it is dipped in the direction of flow. When it is dipped in the direction of flow, it is easier for the flow to lift the rock, penetrate underneath and remove it. Rock that is dipped against the direction of flow will be more difficult to dislodge. The shape of the rock, represented by the length to width ratio *r*, impacts the erodibility of rock in the following manner. Elongated rock will be more difficult to remove than equi-sided blocks of rock. Therefore, large ratios of *r* represent rock that is more difficult to remove because it represents elongated rock shapes. Values of the relative orientation parameter J<sub>s</sub> are provided in Table 4.26.

1.05 J<sub>s</sub> (HEC 18 Table 4.26)

From HEC-18:

Relative orientation, in the case of rock, is a function of the relative shape of the rock and its dip and dip direction relative to the direction of flow. The relative orientation parameter J<sub>s</sub> represents the relative ability of earth material to resist erosion due to the structure of the ground. This parameter is a function of the dip and dip direction of the least favorable discontinuity (most easily eroded) in the rock with respect to the direction of flow, and the shape of the material units. These two variables (orientation and shape) affect the ease by which the stream can penetrate the ground and dislodge individual material units.

Conceptually, the function of the relative orientation parameter J<sub>s</sub> incorporating shape and orientation is as follows. If rock is dipped against the direction flow, it will be more difficult to scour the rock than when it is dipped in the direction of flow. When it is dipped in the direction of flow, it is easier for the flow to lift the rock, penetrate underneath and remove it. Rock that is dipped against the direction of flow will be more difficult to dislodge. The shape of the rock, represented by the length to width ratio *r*, impacts the erodibility of rock in the following manner. Elongated rock will be more difficult to remove than equi-sided blocks of rock. Therefore, large ratios of *r* represent rock that is more difficult to remove because it represents elongated rock shapes. Values of the relative orientation parameter J<sub>s</sub> are provided in Table 4.26.

## MEG-33-19.21 BOWMAN'S RUN DRILLED SHAFT AXIAL CAPACITY CALCULATIONS

### BEDROCK CONDITIONS

The dominate bedrock type at the bridge locations is sandstone with shale partings. Three unconfined compression strength tests were completed on this bedrock. The unconfined compressive strength ( $q_u$ ) of rock at the site is:

$$q_u = 4,050, 5620, \quad 8680 \text{ pounds per square inch (psi)}$$

$$\text{Converting to kips per square foot (ksf) : } q_u = 582, 810, \quad 1,250$$

A compressive strength of 880 ksf was selected based on average testing and field conditions due to the consistent nature of the sandstone.

Since multiple types of bedrock were encountered in the borings, weighted averages based on the length of bedrock observed will be used to develop conservative rock strengths for drilled shaft capacity analysis. A typical  $q_u$  of 600 psi (86 ksf) is applied to shale from testing completed in B-010-0-23. Claystone was not able to be tested due to its fragile nature. A typical  $q_u$  of 250 psi (36 ksf) is applied to claystone based on lab tests performed on other projects and the bedrock conditions.

Drilled shafts typically extend 10 feet into the top of bedrock. For the side resistance calculations, it is assumed shafts extend 8 feet into the top of cored bedrock. The top two feet will consist of severely to highly weathered bedrock and are ignored in shaft resistance calculations as outlined in Section 305.4.1.1 of the 2020 Ohio Department of Transportation Bridge Design Manual. Remaining bedrock observed from rock coring is averaged to determine tip resistance.

### RESISTANCE FACTORS

Drilled shaft resistance factors per ODOT BDM Table 305-1:

- Tip Resistance in Rock = 0.50
- Side Resistance in Rock = 0.55

### UNIT SIDE RESISTANCE

From the AASHTO LRFD 9<sup>th</sup> Edition, the nominal unit side resistance ( $q_s$ ) is determined by:

$$\frac{q_s}{p_a} = C \sqrt{\frac{q_u}{p_a}} \quad (10.8.3.5.4b - 1)$$

Where:

$p_a$  = atmospheric pressure taken as 2.12 ksf

C = regression coefficient taken as 1.0 for normal conditions

For the rear abutment (B-001-0-23, observed approximately 1 ft of interbedded shale):

$$q_s = (2.12 \text{ ksf}) (1.0) \sqrt{\frac{\left(\frac{(880 \text{ ksf} * 7 \text{ ft}) + (86 \text{ ksf} * 1 \text{ ft})}{8 \text{ ft}}\right)}{2.12 \text{ ksf}}} = 40.7 \text{ ksf} \rightarrow 22.4 \text{ ksf factored resistance}$$

For the pier (B-002-0-23, observed approximately 1.5 ft of interbedded shale):

$$q_s = (2.12 \text{ ksf}) (1.0) \sqrt{\frac{\left(\frac{(880 \text{ ksf} * 6.5 \text{ ft}) + (86 \text{ ksf} * 1.5 \text{ ft})}{8 \text{ ft}}\right)}{2.12 \text{ ksf}}} = 39.4 \text{ ksf} \rightarrow 21.7 \text{ ksf factored resistance}$$

For the forward abutment (B-003-0-23, assume highly weathered sandstone has same strength as shale):

$$q_s = (2.12 \text{ ksf}) (1.0) \sqrt{\frac{\left(\frac{(36 \text{ ksf} * 1 \text{ ft}) + (86 \text{ ksf} * 7 \text{ ft})}{8 \text{ ft}}\right)}{2.12 \text{ ksf}}} = 13.0 \text{ ksf} \rightarrow 7.2 \text{ ksf factored resistance}$$

## UNIT TIP RESISTANCE

From the AASHTO LRFD 9<sup>th</sup> Edition, the nominal unit tip resistance ( $q_p$ ) is determined by:

$$q_p = 2.5 q_u \quad (10.8.3.5.4c - 1)$$

For the rear abutment (B-001-0-23, observed approximately 2.5 ft of interbedded shale):

$$q_p = 2.5 \left( \frac{(880 \text{ ksf} * 11.2 \text{ ft}) + (86 \text{ ksf} * 2.5 \text{ ft})}{13.7 \text{ ft}} \right) = 1,837.8 \text{ ksf} \rightarrow 918.9 \text{ ksf factored resistance}$$

For the pier (B-002-0-23):

$$q_p = 2.5 \left( \frac{(880 \text{ ksf} * 2.3 \text{ ft}) + (86 \text{ ksf} * 2 \text{ ft}) + (36 \text{ ksf} * 10 \text{ ft})}{14.3 \text{ ft}} \right) = 446.9 \text{ ksf}$$

→ 223.4 ksf factored resistance

For the forward abutment (B-003-0-23):

$$q_p = 2.5 \left( \frac{(86 \text{ ksf} * 3 \text{ ft}) + (880 \text{ ksf} * 13.2 \text{ ft})}{16.2 \text{ ft}} \right) = 1,832.4 \text{ ksf} \rightarrow 916.2 \text{ ksf factored resistance}$$

$$\text{Converting to kips per square foot (ksf) : } q_u = 390, 638, 904, \quad 1,096$$

A compressive strength of 750 ksf was selected based on average testing and field conditions due to the consistent nature of the sandstone.

Since multiple types of bedrock were encountered in the borings, weighted averages based on the length of bedrock observed will be used to develop conservative rock strengths for drilled shaft capacity analysis. For the pier (B-008-0-23):

$$q_s = (2.12 \text{ ksf}) (1.0) \sqrt{\frac{\left(\frac{(86 \text{ ksf} * 2.5 \text{ ft}) + (36 \text{ ksf} * 5.5 \text{ ft})}{8 \text{ ft}}\right)}{2.12 \text{ ksf}}} = 10.5 \text{ ksf} \rightarrow 5.8 \text{ ksf factored resistance}$$

For the pier (B-008-0-23):

$$q_p = 2.5(36 \text{ ksf}) = 90 \text{ ksf} \rightarrow 45 \text{ ksf}$$

For the forward abutment (B-009-0-23):

$$q_p = 2.5 \left( \frac{(750 \text{ ksf} * 16.1 \text{ ft}) + (86 \text{ ksf} * 0.5 \text{ ft})}{16.6 \text{ ft}} \right) = 1,825 \text{ ksf} \rightarrow 912.5 \text{ ksf}$$

### Lateral Capacity Analyses for bridge at Bowman's Run

#### Rear Abutment

#### Material Parameters

The following table presents the material parameters used for the lateral capacity analyses. The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

#### Material Parameters

Sandy Silt (mod stiff w/o free water)	122	2,000	-	-	-
Bedrock	150	-	-	4,380	86

#### Rear Abutment Loading

- The rear abutment loading provided from the structural team is provided in this appendix. Each abutment consists of 1 row of piles spaced at 16.67' c/c.
- The pile cap is assumed to be rigid; therefore, each pile experiences the same lateral load.
- X and Z represents lateral loads (Z direction being perpendicular to the single row of four piles) while Y represents axial load. The load combinations used in the LPile are as follows:

Load State	Load Direction	Lateral Force (kips)	Lateral Moment (kip-ft)	Axial Load (kips)
Service	X	3.54	124.20	765.80
Service	Z	63.03	0	765.80
Strength	X	4.77	167.70	985.50
Strength	Z	85.10	0	985.50

- To take into account group effects, P-multipliers ( $P_m$ ) were applied to the p-y curves in LPILE. The P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> Edition Section 10.7.2.4 (presented in this appendix). From the structural engineer, the drilled shaft diameter (B) is 3 ft above the socket and 2.5 ft for the socket.

Performed By:	J. Samples	Date:	8/28/2024
Checked By:	G. Khatri	Date:	8/29/2024

- Spacing between rows laterally (X) is 16.67' c/c, which is greater than 5B. P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> edition section 10.7.2.7. Therefore, the P-multiplier at 16.67 ft is taken as same as 5B.
  - Row 1 →  $P_m = 1$
  - Row 2 →  $P_m = 0.85$
  - Row 3 →  $P_m = 0.7$
- Since there is only a single row of piles in the perpendicular (Z) direction,  $P_m = 1.0$  is only needed

- X and Z represents lateral loads (Z direction being perpendicular to the single row of four piles) while Y represents axial load. The load combinations used in the LPILE are as follows:

Load State	Load Direction	Lateral Load (kips)	Lateral Moment (kip-ft)	Axial Load (kips)
Service	X	3.54	124.20	751.80
Service	Z	63.04	0	751.80
Strength	X	4.77	167.70	967.80
Strength	Z	85.10	0	967.80

- To take into account group effects, P-multipliers ( $P_m$ ) were applied to the p-y curves in LPILE. The P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> Edition Section 10.7.2.4 (presented in this appendix). From the structural engineer, the drilled shaft diameter (B) is 3 ft above the socket and 2.5 ft for the socket.
  - Spacing between rows laterally (X) is 16.67' c/c, which is greater than 5B. P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> edition section 10.7.2.7. Therefore, the P-multiplier at 16.67 ft is taken same as 5B.
    - Row 1 →  $P_m = 1$
    - Row 2 →  $P_m = 0.85$
    - Row 3 →  $P_m = 0.7$

Performed By:	J. Samples	Date:	8/28/2024
Checked By:	G. Khatri	Date:	8/29/2024

- Since there is only a single row of piles in the perpendicular (Z) direction,  $P_m = 1.0$  is only needed

## Pier

### Material Parameters

The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

Material	Moist Unit Weight (pcf)	Undrained Cohesion (psf)	Friction Angle (degrees)	Compressive Strength (psi)	RQD (%)
Sandy Silt (mod stiff w/o free water)	122	2,000	-	-	-
Bedrock	150	-	-	4,380	74

### Pier Abutment Loading

- The pier abutment loading provided from the structural team is provided in this appendix. Each abutment consists of 1 row of piles spaced at 16.75' c/c.
- The pile cap is assumed to be rigid; therefore, each pile experiences the same lateral load.
- X and Z represents lateral loads (Z direction being perpendicular to the single row of four piles) while Y represents axial load. The load combinations used in the LPile are as follows:

Load State	Case	Lateral Load (kips)	Lateral Moment (kip-ft)	Axial Load (kips)
Service	I	19.02	319.70	848.90
Strength		23.99	418.80	1102.00

Service	III	17.85	698.60	846.00
Strength		23.13	913.32	1091.00

- To take into account group effects, P-multipliers ( $P_m$ ) were applied to the p-y curves in LPILE. The P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> Edition Section 10.7.2.4 (presented in this appendix). From the structural engineer, the drilled shaft diameter (B) is 4 ft above the socket and 3.5 ft for the socket.
  - Spacing between rows laterally (X) is 16.75' c/c, which is between the 3B and 5B. P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> edition section 10.7.2.7. Therefore, the P-multiplier at 16.75 ft is calculated through interpolation:
    - Row 1 →  $P_m = 0.92$

Performed By:	J. Samples	Date:	8/28/2024
Checked By:	G. Khatri	Date:	8/29/2024

- Row 2 →  $P_m = 0.67$
- Row 3 →  $P_m = 0.54$

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:  
 -----

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.02175642 inches  
 Computed slope at pile head = -0.0004361 radians  
 Maximum bending moment = 1544731. inch-lbs  
 Maximum shear force = -15096. lbs  
 Depth of maximum bending moment = 1.80880000 feet below pile head  
 Depth of maximum shear force = 7.75200000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.02996537 inches  
 Computed slope at pile head = -0.0006043 radians  
 Maximum bending moment = 2087600. inch-lbs  
 Maximum shear force = -20548. lbs  
 Depth of maximum bending moment = 1.80880000 feet below pile head  
 Depth of maximum shear force = 7.75200000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.02328621 inches  
 Computed slope at pile head = -0.0004510 radians  
 Maximum bending moment = 1547379. inch-lbs  
 Maximum shear force = -14725. lbs  
 Depth of maximum bending moment = 1.80880000 feet below pile head  
 Depth of maximum shear force = 8.01040000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.03217620 inches  
 Computed slope at pile head = -0.0006260 radians  
 Maximum bending moment = 2091230. inch-lbs  
 Maximum shear force = -20039. lbs  
 Depth of maximum bending moment = 1.80880000 feet below pile head  
 Depth of maximum shear force = 8.01040000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:  
 -----

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor ( $\phi$ -factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.02526476 inches  
 Computed slope at pile head = -0.0004694 radians  
 Maximum bending moment = 1551265. inch-lbs  
 Maximum shear force = -14359. lbs  
 Depth of maximum bending moment = 2.06720000 feet below pile head  
 Depth of maximum shear force = 8.52720000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.03573665 inches  
 Computed slope at pile head = -0.0006587 radians  
 Maximum bending moment = 2095596. inch-lbs  
 Maximum shear force = -19518. lbs  
 Depth of maximum bending moment = 2.06720000 feet below pile head  
 Depth of maximum shear force = 8.52720000 feet below pile head  
 Number of iterations = 7  
 Number of zero deflection points = 5

Number of pile sections defined = 2  
Total length of pile = 25.840 ft  
Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 4 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

Point No.	Depth Below Pile Head feet	Pile Diameter inches
1	0.000	36.0000
2	15.840	36.0000

y = lateral deflection normal to pile axis

S = pile slope relative to original pile batter angle

R = rotational stiffness applied to pile head

Values of top y vs. pile lengths can be computed only for load types with specified shear loading (Load Types 1, 2, and 3).

Thrust force is assumed to be acting axially for all pile batter angles.

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	765.800	13511.243	0.00300000	-0.00570261
2	985.500	14861.546	0.00300000	-0.00464537

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

1	765.800	9649.562	0.00300000	-0.00404010
2	985.500	10325.067	0.00300000	-0.00311069

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

MEG-33 rear abutment Z direction

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (Ø.65) or spirals (Ø.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.11607823 inches  
 Computed slope at pile head = -0.0011910 radians  
 Maximum bending moment = 3039933. inch-lbs  
 Maximum shear force = 63030. lbs  
 Depth of maximum bending moment = 7.49360000 feet below pile head  
 Depth of maximum shear force = 0.000000 feet below pile head  
 Number of iterations = 18  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether

Pier drilled shaft\_row1

the transverse reinforcing steel bars are tied hoops (Ø.65) or spirals (Ø.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.01784551 inches  
 Computed slope at pile head = -0.0003699 radians  
 Maximum bending moment = 4332585. inch-lbs  
 Maximum shear force = -183635. lbs  
 Depth of maximum bending moment = 4.32000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.02433000 inches  
 Computed slope at pile head = -0.0005007 radians  
 Maximum bending moment = 5769231. inch-lbs  
 Maximum shear force = -248698. lbs  
 Depth of maximum bending moment = 5.28000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 3:

Pile-head deflection = 0.01830928 inches  
 Computed slope at pile head = -0.0003913 radians  
 Maximum bending moment = 4595752. inch-lbs  
 Maximum shear force = -183319. lbs  
 Depth of maximum bending moment = 2.24000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 4:

Pile-head deflection = 0.02609858 inches  
 Computed slope at pile head = -0.0005519 radians  
 Maximum bending moment = 6240181. inch-lbs  
 Maximum shear force = -259430. lbs  
 Depth of maximum bending moment = 2.88000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 5:

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 6:

Pile-head deflection = 0.05444838 inches  
 Computed slope at pile head = -0.0010893 radians  
 Maximum bending moment = 11541227. inch-lbs  
 Maximum shear force = -486228. lbs  
 Depth of maximum bending moment = 4.00000000 feet below pile head  
 Depth of maximum shear force = 7.20000000 feet below pile head  
 Number of iterations = 13  
 Number of zero deflection points = 4

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether

Pier drilled shaft\_row2

the transverse reinforcing steel bars are tied hoops (Ø.65) or spirals (Ø.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

 Computed Values of Pile Loading and Deflection  
 for Lateral Loading for Load Case Number 1

Pile-head conditions are Shear and Moment (Loading Type 1)

Shear force at pile head = 19020.0 lbs  
 Applied moment at pile head = 3836400.0 in-lbs  
 Axial thrust load on pile head = 848900.0 lbs

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.01870880 inches  
 Computed slope at pile head = -0.0003824 radians  
 Maximum bending moment = 4524863. inch-lbs  
 Maximum shear force = -194306. lbs  
 Depth of maximum bending moment = 6.08000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.02576007 inches  
 Computed slope at pile head = -0.0005199 radians  
 Maximum bending moment = 6027350. inch-lbs  
 Maximum shear force = -260571. lbs  
 Depth of maximum bending moment = 6.08000000 feet below pile head

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 3:

Pile-head deflection = 0.01918475 inches  
 Computed slope at pile head = -0.0004040 radians  
 Maximum bending moment = 4648022. inch-lbs  
 Maximum shear force = -194078. lbs  
 Depth of maximum bending moment = 3.20000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 4:

Pile-head deflection = 0.02758744 inches  
 Computed slope at pile head = -0.0005718 radians  
 Maximum bending moment = 6328257. inch-lbs  
 Maximum shear force = -270524. lbs  
 Depth of maximum bending moment = 4.00000000 feet below pile head  
 Depth of maximum shear force = 7.20000000 feet below pile head  
 Number of iterations = 7  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 6:

M = bending moment applied to pile head

y = lateral deflection normal to pile axis

S = pile slope relative to original pile batter angle

R = rotational stiffness applied to pile head

Values of top y vs. pile lengths can be computed only for load types with specified shear loading (Load Types 1, 2, and 3).

Thrust force is assumed to be acting axially for all pile batter angles.

Definitions of Run Messages and Notes:

-----

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether

Pier drilled shaft\_row3

the transverse reinforcing steel bars are tied hoops (Ø.65) or spirals (Ø.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.01916775 inches  
 Computed slope at pile head = -0.0003890 radians  
 Maximum bending moment = 4659804. inch-lbs  
 Maximum shear force = -199976. lbs  
 Depth of maximum bending moment = 6.08000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.02648774 inches  
 Computed slope at pile head = -0.0005297 radians  
 Maximum bending moment = 6173298. inch-lbs  
 Maximum shear force = -267706. lbs

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 3:

Pile-head deflection = 0.01965011 inches  
 Computed slope at pile head = -0.0004107 radians  
 Maximum bending moment = 4694835. inch-lbs  
 Maximum shear force = -199796. lbs  
 Depth of maximum bending moment = 3.84000000 feet below pile head  
 Depth of maximum shear force = 7.04000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 4:

Pile-head deflection = 0.02833593 inches  
 Computed slope at pile head = -0.0005819 radians  
 Maximum bending moment = 6408116. inch-lbs  
 Maximum shear force = -277845. lbs  
 Depth of maximum bending moment = 4.96000000 feet below pile head  
 Depth of maximum shear force = 7.20000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 4

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual

stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 5:

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 6:

Pile-head deflection = 0.06718475 inches  
 Computed slope at pile head = -0.0012666 radians  
 Maximum bending moment = 11913785. inch-lbs  
 Maximum shear force = -496686. lbs  
 Depth of maximum bending moment = 6.08000000 feet below pile head  
 Depth of maximum shear force = 7.52000000 feet below pile head  
 Number of iterations = 35  
 Number of zero deflection points = 3

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
----	-----	-----	-----	-----
1	751.800	9593.444	0.00300000	-0.00411050
2	967.800	10298.326	0.00300000	-0.00317053

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

MEG-33 forward abutment X direction row1

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00057808 inches  
 Computed slope at pile head = -0.0001026 radians  
 Maximum bending moment = 1490400. inch-lbs  
 Maximum shear force = -91249. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.80000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.00081960 inches  
 Computed slope at pile head = -0.0001453 radians  
 Maximum bending moment = 2012400. inch-lbs  
 Maximum shear force = -124655. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.80000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

Number of pile sections defined = 1  
Total length of pile = 10.000 ft  
Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 2 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

V = shear force applied normal to pile axis

M = bending moment applied to pile head

y = lateral deflection normal to pile axis

S = pile slope relative to original pile batter angle

R = rotational stiffness applied to pile head

Values of top y vs. pile lengths can be computed only for load types with specified shear loading (Load Types 1, 2, and 3).

Thrust force is assumed to be acting axially for all pile batter angles.

Definitions of Run Messages and Notes:

-----

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
----	-----	-----	-----	-----

2	967.800	10298.326	0.00300000	-0.00317053

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

MEG-33 forward abutment X direction row2

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00057808 inches  
 Computed slope at pile head = -0.0001026 radians  
 Maximum bending moment = 1490400. inch-lbs  
 Maximum shear force = -91249. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.80000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Computed slope at pile head = -0.0001483 radians  
 Maximum bending moment = 2012400. inch-lbs  
 Maximum shear force = -124764. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.80000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
----	-----	-----	-----	-----

2	967.800	10298.326	0.00300000	-0.00317053

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

MEG-33 forward abutment X direction row3

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00057808 inches  
 Computed slope at pile head = -0.0001026 radians  
 Maximum bending moment = 1490400. inch-lbs  
 Maximum shear force = -91249. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.80000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	751.800	9593.444	0.00300000	-0.00411050
2	967.800	10298.326	0.00300000	-0.00317053

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00025480 inches  
 Computed slope at pile head = -0.0000238 radians  
 Maximum bending moment = 235195. inch-lbs  
 Maximum shear force = 63040. lbs  
 Depth of maximum bending moment = 0.70000000 feet below pile head  
 Depth of maximum shear force = 0.000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses

MEG-33 forward abutment Z direction  
 are computed only for elastic sections only and do not equal the actual  
 stresses in concrete and steel. Stresses in concrete and steel may be inter-  
 polated from the output for nonlinear bending properties relative to the  
 magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.00034823 inches  
 Computed slope at pile head = -0.0000329 radians  
 Maximum bending moment = 314009. inch-lbs  
 Maximum shear force = 85100. lbs  
 Depth of maximum bending moment = 0.70000000 feet below pile head  
 Depth of maximum shear force = 0.000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

LATERAL LOAD ANALYSIS**

## MEG-33-19.21

### Lateral Capacity Analyses for bridge at Oldtown Creek

#### Rear Abutment

#### Material Parameters

The following table presents the material parameters used for the lateral capacity analyses. The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

#### Material Parameters

Material	Moist Unit Weight (pcf)	Undrained Cohesion (psf)	Friction Angle (degrees)	Compressive Strength (psi)	RQD (%)
Fill (mod stiff w/o free water)	125	2,500	-	-	-
Gravel and stone fragments with sand, silt and clay (sand)	122	-	32	-	-
Silt and Clay (mod stiff w/o free water)	125	2,500	-	-	-
Bedrock	145	-	-	3,820	77

#### Rear Abutment Loading

- The rear abutment loading provided from the structural team is provided in this appendix. Each abutment consists of 1 row of piles spaced at 16' c/c.
- The pile cap is assumed to be rigid; therefore, each pile experiences the same lateral load.
- X and Z represents lateral loads (Z direction being perpendicular to the single row of four piles) while Y represents axial load. The load combinations used in the LPile are as follows:

Load State	Load Direction	Lateral Force (kips)	Lateral Moment (kip-ft)	Axial Load (kips)
Service	X	-1.80	363.60	774.50
Service	Z	105.92	0.00	774.50
Strength	X	-2.42	490.80	996.60
Strength	Z	142.96	0.00	996.60

Performed By:	G. Khatri	Date:	8/29/2024
Checked By:	J. Samples	Date:	8/30/2024

- To take into account group effects, P-multipliers ( $P_m$ ) were applied to the p-y curves in LPILE. The P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> Edition Section 10.7.2.4 (presented in this appendix). From the structural engineer, the drilled shaft diameter (B) is 3 ft above the socket and 2.5 ft for the socket.
  - Spacing between rows laterally (Z) is 16' c/c, which is greater than 5B. P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> edition section 10.7.2.7. Therefore, the P-multiplier at 16.00 ft is taken as same as 5B.
    - Row 1 →  $P_m = 1$
    - Row 2 →  $P_m = 0.85$
    - Row 3 →  $P_m = 0.7$
  - Since there is only a single row of piles in the perpendicular (X) direction,  $P_m = 1.0$  is only needed

## Forward Abutment

The forward abutment consists of the bedrock at the ground surface.

The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

## Pier

The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

## Pier Abutment Loading

- The pier abutment loading provided from the structural team is provided in this appendix. Each abutment consists of 1 row of piles spaced at 16' c/c.
- The pile cap is assumed to be rigid; therefore, each pile experiences the same lateral load.
- X and Z represents lateral loads (Z direction being perpendicular to the single row of four piles) while Y represents axial load. The load combinations used in the LPILE are as follows:

Load State	Case	Lateral Load (kips)	Lateral Moment (kip-ft)	Axial Load (kips)
Service	I	-18.61	-864.40	775.40
Strength		-24.30	-1133.00	995.70
Service	III	10.71	-475.10	1030.00
Strength		14.41	639.60	1340.00

- To take into account group effects, P-multipliers ( $P_m$ ) were applied to the p-y curves in LPILE. The P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> Edition Section 10.7.2.4 (presented in this appendix). From the structural engineer, the drilled shaft diameter (B) is 5 ft above the socket and 4.5 ft for the socket.
  - Spacing between rows laterally (Z) is 16' c/c, which is between the 3B and 5B. P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> edition section 10.7.2.7. Therefore, the P-multiplier at 16.00 ft is calculated as follows:
    - Row 1 →  $P_m = 0.82$
    - Row 2 →  $P_m = 0.45$

Performed By:	G. Khatri	Date:	8/29/2024
Checked By:	J. Samples	Date:	8/30/2024

- Row 3 →  $P_m = 0.34$

Summary of Results for Nominal Moment Capacity for Section 1  
-----

Moment values interpolated at maximum compressive strain = 0.003  
or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	13568.309	0.00300000	-0.00565676
2	996.600	14924.592	0.00300000	-0.00459709

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.  
 Y = stress in reinforcing steel has reached yield stress.  
 T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.  
 Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Axial Thrust Force = 774.500 kips

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	9683.598	0.00300000	-0.00399835
2	996.600	10339.541	0.00300000	-0.00307360

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual

stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.06678681 inches  
 Computed slope at pile head = -0.0013208 radians  
 Maximum bending moment = 4381982. inch-lbs  
 Maximum shear force = 46920. lbs  
 Depth of maximum bending moment = 0.87750000 feet below pile head  
 Depth of maximum shear force = 20.18250000 feet below pile head  
 Number of iterations = 13  
 Number of zero deflection points = 6

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.11308877 inches  
 Computed slope at pile head = -0.0019777 radians  
 Maximum bending moment = 5917382. inch-lbs  
 Maximum shear force = 55376. lbs  
 Depth of maximum bending moment = 0.87750000 feet below pile head  
 Depth of maximum shear force = 20.18250000 feet below pile head  
 Number of iterations = 15  
 Number of zero deflection points = 6

Pile Structural Properties and Geometry  
-----

Number of pile sections defined = 2

Total length of pile = 29.250 ft  
 Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 4 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

Point No.	Depth Below Pile Head feet	Pile Diameter inches
1	0.000	36.0000
2	19.250	36.0000
3	19.250	30.0000
4	29.250	30.0000

Input Structural Properties for Pile Sections:  
 -----

Pile Section No. 1:

Section 1 is a round drilled shaft, bored pile, or CIDH pile

Length of section = 19.250000 ft  
 Shaft Diameter = 36.000000 in

Pile Section No. 2:

Section 2 is a round drilled shaft, bored pile, or CIDH pile

Length of section = 10.000000 ft  
 Shaft Diameter = 30.000000 in

V = shear force applied normal to pile axis

M = bending moment applied to pile head

y = lateral deflection normal to pile axis

S = pile slope relative to original pile batter angle

R = rotational stiffness applied to pile head

Values of top y vs. pile lengths can be computed only for load types with specified shear loading (Load Types 1, 2, and 3).

Thrust force is assumed to be acting axially for all pile batter angles.

Definitions of Run Messages and Notes:

-----

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Summary of Results for Nominal Moment Capacity for Section 1  
-----

Moment values interpolated at maximum compressive strain = 0.003  
or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	13568.309	0.00300000	-0.00565676
2	996.600	14924.592	0.00300000	-0.00459709

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Axial Load No.	Resist. Factor	Nominal Ax. Thrust kips	Nominal Moment Cap in-kips	Ult. (Fac) Ax. Thrust kips	Ult. (Fac) Moment Cap in-kips	Bend. Stiff. at Ult Mom kip-in^2

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.  
 Y = stress in reinforcing steel has reached yield stress.  
 T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.  
 Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	9683.598	0.00300000	-0.00399835
2	996.600	10339.541	0.00300000	-0.00307360

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual

stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.07840283 inches  
 Computed slope at pile head = -0.0014013 radians  
 Maximum bending moment = 4382550. inch-lbs  
 Maximum shear force = 43092. lbs  
 Depth of maximum bending moment = 0.87750000 feet below pile head  
 Depth of maximum shear force = 20.18250000 feet below pile head  
 Number of iterations = 14  
 Number of zero deflection points = 6

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Depth of maximum shear force = 20.18250000 feet below pile head

Summary of Results for Nominal Moment Capacity for Section 1  
-----

Moment values interpolated at maximum compressive strain = 0.003  
or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	13568.309	0.00300000	-0.00565676
2	996.600	14924.592	0.00300000	-0.00459709

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Axial Load No.	Resist. Factor	Nominal Ax. Thrust kips	Nominal Moment Cap in-kips	Ult. (Fac) Ax. Thrust kips	Ult. (Fac) Moment Cap in-kips	Bend. Stiff. at Ult Mom kip-in^2

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.  
 Y = stress in reinforcing steel has reached yield stress.  
 T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.  
 Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Axial Thrust Force = 774.500 kips

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	9683.598	0.00300000	-0.00399835
2	996.600	10339.541	0.00300000	-0.00307360

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual

stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.09503208 inches  
 Computed slope at pile head = -0.0015111 radians  
 Maximum bending moment = 4383350. inch-lbs  
 Maximum shear force = 35524. lbs  
 Depth of maximum bending moment = 0.87750000 feet below pile head  
 Depth of maximum shear force = 20.18250000 feet below pile head  
 Number of iterations = 14  
 Number of zero deflection points = 6

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.15903586 inches  
 Computed slope at pile head = -0.0022833 radians  
 Maximum bending moment = 5922556. inch-lbs  
 Maximum shear force = -36410. lbs  
 Depth of maximum bending moment = 0.87750000 feet below pile head  
 Depth of maximum shear force = 11.99250000 feet below pile head  
 Number of iterations = 14  
 Number of zero deflection points = 6

Number of pile sections defined = 2

Total length of pile = 29.250 ft  
 Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 4 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	13568.309	0.00300000	-0.00565676
2	996.600	14924.592	0.00300000	-0.00459709

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.  
Y = stress in reinforcing steel has reached yield stress.  
T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.  
Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
Position of neutral axis is measured from edge of compression side of pile.  
Compressive stresses and strains are positive in sign.  
Tensile stresses and strains are negative in sign.

Axial Thrust Force = 774.500 kips

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	774.500	9683.598	0.00300000	-0.00399835
2	996.600	10339.541	0.00300000	-0.00307360

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual

stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.39716117 inches  
 Computed slope at pile head = -0.0032525 radians  
 Maximum bending moment = 6015360. inch-lbs  
 Maximum shear force = -112704. lbs  
 Depth of maximum bending moment = 9.06750000 feet below pile head  
 Depth of maximum shear force = 19.89000000 feet below pile head  
 Number of iterations = 19  
 Number of zero deflection points = 5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Depth of maximum shear force = 19.89000000 feet below pile head  
 Number of iterations = 23

Y = stress in reinforcing steel has reached yield stress.

T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.

Z = depth of tensile zone in concrete section is less than 10 percent of

section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.

Position of neutral axis is measured from edge of compression side of pile.

Compressive stresses and strains are positive in sign.

Tensile stresses and strains are negative in sign.

Axial Thrust Force = 714.600 kips

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection	=	0.00060263 inches
Computed slope at pile head	=	-0.0001017 radians
Maximum bending moment	=	1416000. inch-lbs
Maximum shear force	=	-83862. lbs
Depth of maximum bending moment	=	0.000000 feet below pile head
Depth of maximum shear force	=	0.80000000 feet below pile head
Number of iterations	=	6
Number of zero deflection points	=	5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Maximum shear force = -114209. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.90000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection	=	0.00062440 inches
Computed slope at pile head	=	-0.0001035 radians
Maximum bending moment	=	1416000. inch-lbs
Maximum shear force	=	-83805. lbs

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.00098321 inches  
 Computed slope at pile head = -0.0001541 radians  
 Maximum bending moment = 1920000. inch-lbs  
 Maximum shear force = -113965. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 0.90000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

Number of pile sections defined = 1

Total length of pile = 10.000 ft  
 Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 2 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

Point No.	Depth Below Pile Head feet	Pile Diameter inches

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection	=	0.00067695 inches
Computed slope at pile head	=	-0.0001077 radians
Maximum bending moment	=	1416000. inch-lbs
Maximum shear force	=	-83691. lbs
Depth of maximum bending moment	=	0.000000 feet below pile head
Depth of maximum shear force	=	0.90000000 feet below pile head
Number of iterations	=	6
Number of zero deflection points	=	5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Computed slope at pile head = -0.0001620 radians  
 Maximum bending moment = 1920000. inch-lbs  
 Maximum shear force = -112776. lbs  
 Depth of maximum bending moment = 0.000000 feet below pile head  
 Depth of maximum shear force = 1.00000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of

section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.

Position of neutral axis is measured from edge of compression side of pile.

Compressive stresses and strains are positive in sign.

Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	714.600	9439.535	0.00300000	-0.00430146
2	921.400	10195.452	0.00300000	-0.00334320

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection	=	0.00027099 inches
Computed slope at pile head	=	-0.0000245 radians
Maximum bending moment	=	234925. inch-lbs
Maximum shear force	=	60820. lbs
Depth of maximum bending moment	=	0.70000000 feet below pile head
Depth of maximum shear force	=	0.000000 feet below pile head
Number of iterations	=	6
Number of zero deflection points	=	5

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Note that the values of moment capacity in the table above are not factored by a strength reduction factor ( $\phi$ -factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Summary of Results for Nominal Moment Capacity for Section 2

Moment values interpolated at maximum compressive strain = 0.003  
or maximum developed moment if pile fails at smaller strains.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction

factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

#### Output Summary for Load Case No. 2:

Pile-head deflection = 0.09584082 inches  
 Computed slope at pile head = -0.0009525 radians  
 Maximum bending moment = 14205369. inch-lbs  
 Maximum shear force = -92662. lbs  
 Depth of maximum bending moment = 3.72000000 feet below pile head  
 Depth of maximum shear force = 18.60000000 feet below pile head  
 Number of iterations = 15  
 Number of zero deflection points = 2

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 3:

Pile-head deflection = 0.02686068 inches  
 Computed slope at pile head = -0.0003296 radians  
 Maximum bending moment = 5963493. inch-lbs  
 Maximum shear force = -37660. lbs  
 Depth of maximum bending moment = 3.10000000 feet below pile head  
 Depth of maximum shear force = 13.02000000 feet below pile head  
 Number of iterations = 7  
 Number of zero deflection points = 3

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 4:

Pile-head deflection = 0.04065499 inches  
 Computed slope at pile head = -0.0004724 radians  
 Maximum bending moment = 8021764. inch-lbs  
 Maximum shear force = -51041. lbs  
 Depth of maximum bending moment = 3.10000000 feet below pile head  
 Depth of maximum shear force = 14.26000000 feet below pile head  
 Number of iterations = 10  
 Number of zero deflection points = 3

Note that the values of moment capacity in the table above are not factored by a strength reduction factor ( $\phi$ -factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

-----

C = concrete in section has cracked in tension.

Y = stress in reinforcing steel has reached yield stress.  
 T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.  
 Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Summary of Results for Nominal Moment Capacity for Section 2

Moment values interpolated at maximum compressive strain = 0.003  
or maximum developed moment if pile fails at smaller strains.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction

factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

#### Output Summary for Load Case No. 2:

Pile-head deflection = 0.15953387 inches  
 Computed slope at pile head = -0.0012463 radians  
 Maximum bending moment = 14475266. inch-lbs  
 Maximum shear force = -140083. lbs  
 Depth of maximum bending moment = 5.27000000 feet below pile head  
 Depth of maximum shear force = 22.94000000 feet below pile head  
 Number of iterations = 14  
 Number of zero deflection points = 2

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 3:

Pile-head deflection = 0.04136272 inches  
 Computed slope at pile head = -0.0004061 radians  
 Maximum bending moment = 6009088. inch-lbs  
 Maximum shear force = -37986. lbs  
 Depth of maximum bending moment = 4.03000000 feet below pile head  
 Depth of maximum shear force = 19.22000000 feet below pile head  
 Number of iterations = 11  
 Number of zero deflection points = 2

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 4:

 Computed slope at pile head = -0.0006036 radians  
 Maximum bending moment = 8117076. inch-lbs  
 Maximum shear force = -52001. lbs  
 Depth of maximum bending moment = 4.34000000 feet below pile head  
 Depth of maximum shear force = 21.39000000 feet below pile head

Pile Structural Properties and Geometry  
-----

Number of pile sections defined = 2

Total length of pile = 31.000 ft  
Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 4 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

Point No.	Depth Below Pile Head feet	Pile Diameter inches
1	0.000	60.0000
2	21.000	60.0000

M = bending moment applied to pile head

y = lateral deflection normal to pile axis

S = pile slope relative to original pile batter angle

R = rotational stiffness applied to pile head

Values of top y vs. pile lengths can be computed only for load types with specified shear loading (Load Types 1, 2, and 3).

Thrust force is assumed to be acting axially for all pile batter angles.

Summary of Results for Nominal Moment Capacity for Section 1

Moment values interpolated at maximum compressive strain = 0.003  
or maximum developed moment if pile fails at smaller strains.

Note that the values of moment capacity in the table above are not factored by a strength reduction factor ( $\phi$ -factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

-----

C = concrete in section has cracked in tension.

Y = stress in reinforcing steel has reached yield stress.  
 T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.  
 Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Axial Thrust Force = 775.400 kips

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction

factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

#### Output Summary for Load Case No. 2:

Pile-head deflection = 0.19466513 inches  
 Computed slope at pile head = -0.0013968 radians  
 Maximum bending moment = 14669473. inch-lbs  
 Maximum shear force = -177430. lbs  
 Depth of maximum bending moment = 6.51000000 feet below pile head  
 Depth of maximum shear force = 23.56000000 feet below pile head  
 Number of iterations = 14  
 Number of zero deflection points = 2

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 3:

Pile-head deflection = 0.05238553 inches  
 Computed slope at pile head = -0.0004580 radians  
 Maximum bending moment = 6047222. inch-lbs  
 Maximum shear force = -40025. lbs  
 Depth of maximum bending moment = 4.65000000 feet below pile head  
 Depth of maximum shear force = 21.70000000 feet below pile head  
 Number of iterations = 13  
 Number of zero deflection points = 2

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

### Lateral Capacity Analyses for bridge at Bridge 3

#### Rear Abutment

#### Material Parameters

The following table presents the material parameters used for the lateral capacity analyses. The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

#### Material Parameters

Material	Moist Unit Weight (pcf)	Undrained Cohesion (psf)	Friction Angle (degrees)	Compressive Strength (psi)	RQD (%)
Sandy Silt (mod stiff w/o free water)	122	2,000	-	-	-
Bedrock	150	-	-	4,380	69

#### Rear Abutment Loading

- The rear abutment loading provided from the structural team is provided in this appendix. Each abutment consists of 1 row of piles spaced at 12.5' c/c.
- The pile cap is assumed to be rigid; therefore, each pile experiences the same lateral load.
- X and Z represents lateral loads (Z direction being perpendicular to the single row of four piles) while Y represents axial load. The load combinations used in the LPILE are as follows:

#### Rear Abutment Loads

Load State	Lateral Load (kips)	Lateral Moment (kip-ft)	Axial Load (kips)
Service	86.00	571.64	637.40
Strength	131.50	874.40	852.30

- To take into account group effects, P-multipliers ( $P_m$ ) were applied to the p-y curves in LPILE. The P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> Edition Section 10.7.2.4 (presented in this appendix). From the structural engineer, the drilled shaft diameter (B) is 4.5 ft above the socket and 4 ft for the socket.
  - Spacing between rows laterally (Z) is 12.25' c/c, which is less than 3B. P-multipliers are provided in AASHTO LRFD 9<sup>th</sup> edition section 10.7.2.7. Therefore, the P-multiplier at 12.25 ft is taken as same as 3B.

- Row 1 →  $P_m = 0.8$
- Row 2 →  $P_m = 0.4$
- Row 3 →  $P_m = 0.3$
- Since there is only a single row of piles in the perpendicular (X) direction,  $P_m = 1.0$  is only needed

### **Rear Abutment LPile Results**

The following table summarizes the LPile results for each load and  $P_m$  combination discussed at the rear abutment:

#### **LPile Results**

### **Forward Abutment**

The forward consists of the bedrock at the ground surface. The material parameters are based on information found in the Ohio Department of Transportation (ODOT) Geotechnical Design Manual (GDM) and boring logs (blow counts). The groundwater table depth at the pile head was assumed to be below the top of the rock.

Definitions of Run Messages and Notes:  
 -----

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	33585.679	0.00300000	-0.01015581
2	852.300	36888.690	0.00300000	-0.00894223

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- 
- C = concrete in section has cracked in tension.
  - Y = stress in reinforcing steel has reached yield stress.
  - T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
  - Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	28399.776	0.00300000	-0.00854768
2	852.300	31051.163	0.00300000	-0.00743381

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.54787084 inches  
 Computed slope at pile head = -0.0045901 radians  
 Maximum bending moment = 20638556. inch-lbs  
 Maximum shear force = -752202. lbs  
 Depth of maximum bending moment = 12.50000000 feet below pile head  
 Depth of maximum shear force = 16.50000000 feet below pile head  
 Number of iterations = 26  
 Number of zero deflection points = 3

Number of pile sections defined = 2  
 Total length of pile = 25.000 ft  
 Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 4 points.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	33585.679	0.00300000	-0.01015581
2	852.300	36888.690	0.00300000	-0.00894223

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- 
- C = concrete in section has cracked in tension.
  - Y = stress in reinforcing steel has reached yield stress.
  - T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
  - Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	28399.776	0.00300000	-0.00854768

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.40204030 inches

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	33585.679	0.00300000	-0.01015581
2	852.300	36888.690	0.00300000	-0.00894223

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- 
- C = concrete in section has cracked in tension.
  - Y = stress in reinforcing steel has reached yield stress.
  - T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
  - Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	28399.776	0.00300000	-0.00854768
2	852.300	31051.163	0.00300000	-0.00743381

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.48449243 inches  
 Computed slope at pile head = -0.0035832 radians  
 Maximum bending moment = 17306920. inch-lbs  
 Maximum shear force = -614095. lbs  
 Depth of maximum bending moment = 15.00000000 feet below pile head

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 1.05678914 inches  
 Computed slope at pile head = -0.0076621 radians  
 Maximum bending moment = 28539760. inch-lbs  
 Maximum shear force = -923049. lbs  
 Depth of maximum bending moment = 15.25000000 feet below pile head  
 Depth of maximum shear force = 17.75000000 feet below pile head  
 Number of iterations = 43  
 Number of zero deflection points = 3

Definitions of Run Messages and Notes:

- C = concrete in section has cracked in tension.
- Y = stress in reinforcing steel has reached yield stress.
- T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
- Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

Axial Thrust Force = 637.400 kips

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	33585.679	0.00300000	-0.01015581
2	852.300	36888.690	0.00300000	-0.00894223

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Definitions of Run Messages and Notes:

- 
- C = concrete in section has cracked in tension.
  - Y = stress in reinforcing steel has reached yield stress.
  - T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
  - Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 2  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	637.400	28399.776	0.00300000	-0.00854768
2	852.300	31051.163	0.00300000	-0.00743381

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318, or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

Notes: The F0 integral of Layer n+1 equals the sum of the F0 and F1 integrals for Layer n. Layering correction equivalent depths are computed only for soil types with both shallow-depth and deep-depth expressions for peak lateral load transfer. These soil types are soft and stiff clays, non-liquefied sands, and cemented c-phi soil.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.15578703 inches  
 Computed slope at pile head = -0.0014522 radians  
 Maximum bending moment = 11681931. inch-lbs  
 Maximum shear force = -363290. lbs

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

Pile-head deflection = 0.44686920 inches  
 Computed slope at pile head = -0.0039306 radians  
 Maximum bending moment = 19069905. inch-lbs  
 Maximum shear force = -668064. lbs  
 Depth of maximum bending moment = 10.50000000 feet below pile head  
 Depth of maximum shear force = 16.25000000 feet below pile head  
 Number of iterations = 30  
 Number of zero deflection points = 3

-----  
 Number of pile sections defined = 1  
 Total length of pile = 10.000 ft  
 Depth of ground surface below top of pile = 0.0000 ft

Pile diameters used for p-y curve computations are defined using 2 points.

p-y curves are computed using pile diameter values interpolated with depth over the length of the pile. A summary of values of pile diameter vs. depth follows.

Point No.	Depth Below Pile Head feet	Pile Diameter inches
1	0.000	30.0000
2	10.000	30.0000

V = shear force applied normal to pile axis

M = bending moment applied to pile head

y = lateral deflection normal to pile axis

S = pile slope relative to original pile batter angle

R = rotational stiffness applied to pile head

Values of top y vs. pile lengths can be computed only for load types with specified shear loading (Load Types 1, 2, and 3).

Thrust force is assumed to be acting axially for all pile batter angles.

MEG-33 forward abutment X&Z direction row 1

- 
- C = concrete in section has cracked in tension.
  - Y = stress in reinforcing steel has reached yield stress.
  - T = ACI 318 criteria for tension-controlled section met, tensile strain in reinforcement exceeds 0.005 while simultaneously compressive strain in concrete more than 0.003. See ACI 318-14, Section 21.2.3.
  - Z = depth of tensile zone in concrete section is less than 10 percent of section depth.

Bending Stiffness (EI) = Computed Bending Moment / Curvature.  
 Position of neutral axis is measured from edge of compression side of pile.  
 Compressive stresses and strains are positive in sign.  
 Tensile stresses and strains are negative in sign.

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	756.200	9611.191	0.00300000	-0.00408816
2	1022.640	10370.558	0.00300000	-0.00298995

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318,

or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00039069 inches  
 Computed slope at pile head = -0.0000609 radians  
 Maximum bending moment = 770048. inch-lbs  
 Maximum shear force = -47901. lbs  
 Depth of maximum bending moment = 0.20000000 feet below pile head  
 Depth of maximum shear force = 0.90000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	756.200	9611.191	0.00300000	-0.00408816

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318,

MEG-33 forward abutment X direction row 2

or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00039069 inches  
 Computed slope at pile head = -0.0000609 radians  
 Maximum bending moment = 770048. inch-lbs  
 Maximum shear force = -47901. lbs  
 Depth of maximum bending moment = 0.20000000 feet below pile head

 Summary of Results for Nominal Moment Capacity for Section 1  
 -----

Moment values interpolated at maximum compressive strain = 0.003  
 or maximum developed moment if pile fails at smaller strains.

Load No.	Axial Thrust kips	Nominal Mom. Cap. in-kip	Max. Comp. Strain	Max. Tens. Strain
1	756.200	9611.191	0.00300000	-0.00408816
2	1022.640	10370.558	0.00300000	-0.00298995

Note that the values of moment capacity in the table above are not factored by a strength reduction factor (phi-factor).

In ACI 318, the value of the strength reduction factor depends on whether the transverse reinforcing steel bars are tied hoops (0.65) or spirals (0.75).

The above values should be multiplied by the appropriate strength reduction factor to compute ultimate moment capacity according to ACI 318,

or the value required by the design standard being followed.

The following table presents factored moment capacities and corresponding bending stiffnesses computed for common resistance factor values used for reinforced concrete sections.

\* This analysis computed pile response using nonlinear moment-curvature relationships. Values of total stress due to combined axial and bending stresses are computed only for elastic sections only and do not equal the actual stresses in concrete and steel. Stresses in concrete and steel may be interpolated from the output for nonlinear bending properties relative to the magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 1:

Pile-head deflection = 0.00039069 inches  
 Computed slope at pile head = -0.0000609 radians  
 Maximum bending moment = 770048. inch-lbs  
 Maximum shear force = -47901. lbs  
 Depth of maximum bending moment = 0.20000000 feet below pile head  
 Depth of maximum shear force = 0.90000000 feet below pile head  
 Number of iterations = 6  
 Number of zero deflection points = 5

 stresses in concrete and steel. Stresses in concrete and steel may be inter-  
 polated from the output for nonlinear bending properties relative to the  
 magnitude of bending moment developed in the pile.

Output Summary for Load Case No. 2:

 Computed slope at pile head = -0.0000989 radians  
 Maximum bending moment = 1199735. inch-lbs  
 Maximum shear force = -75640. lbs  
 Depth of maximum bending moment = 0.20000000 feet below pile head  
 Depth of maximum shear force = 0.90000000 feet below pile head

**Construction Rate Analysis - Station 1353+00**

Because the short-term factor of safety was less than the ODOT required minimum of 1.3, a controlled rate of fill should be used. Assume that the percent consolidation (U) is directly proportional to the ratio of short term and long term factors of safety.

$$U_{req} = [(FS_{req} - FS_{ST}) / (FS_{LT} - FS_{ST})] \times 100\%$$

- where:  $U_{req}$  = required percent consolidation  
 $FS_{required}$  = required short term factor of safety = 1.30  
 $FS_{short\ term}$  = calculated short term factor of safety = 1.27  
 $FS_{long\ term}$  = calculated short term factor of safety = 1.71

$$U_{req} = [(FS_{req} - FS_{ST}) / (FS_{LT} - FS_{ST})] \times 100\% = 6.82\ \text{percent}$$

Estimate the time required for the required percent consolidation to occur.

$$t_v = T_v(D_p)^2 / C_v$$

- where:  $t_v$  = time for required consolidation to occur  
 $T_v$  = time factor for required % consolidation = 0.0039  
 $D_p$  = drainage path (feet) = 14.28 assuming one-way drainage

$$t_v = T_v(D_p)^2 / C_v = 1.12\ \text{days}$$

Estimate the permissible construction rate.

**Construction Rate Analysis - Station 1367+50**

Because the short-term factor of safety was less than the ODOT required minimum of 1.3, a controlled rate of fill should be used. Assume that the percent consolidation (U) is directly proportional to the ratio of short term and long term factors of safety.

$$U_{req} = [(FS_{req} - FS_{ST}) / (FS_{LT} - FS_{ST})] \times 100\%$$

- where:  $U_{req}$  = required percent consolidation  
 $FS_{required}$  = required short term factor of safety = 1.30  
 $FS_{short\ term}$  = calculated short term factor of safety = 1.08  
 $FS_{long\ term}$  = calculated short term factor of safety = 1.61

$$U_{req} = [(FS_{req} - FS_{ST}) / (FS_{LT} - FS_{ST})] \times 100\% = 41.5\ \text{percent}$$

Estimate the time required for the required percent consolidation to occur.

$$t_v = T_v(D_p)^2 / C_v$$

- where:  $t_v$  = time for required consolidation to occur  
 $T_v$  = time factor for required % consolidation = 0.1350  
 $D_p$  = drainage path (feet) = 16.25 assuming one-way drainage  
 $C_v$  = coefficient of consolidation (ft<sup>2</sup>/day) = 0.6 based on average LL  
Average LL = 23

$$t_v = T_v(D_p)^2 / C_v = 59.4\ \text{days}$$

Estimate the permissible construction rate.

$$\text{Permissible Construction Rate} = \frac{\text{Fill Height} \times 7\ \text{days per week}}{t_v}$$

where: Fill Height = 29 feet

$$\text{Permissible Construction Rate} = 3.4\ \text{feet per week}$$

**RESULTS OF ROTATIONAL STABILITY ANALYSIS**

Results in the tables below represent critical circles identified between specified points on entry and exit. (Theta-exit set to 50.00 deg.)  
 The most critical circle is obtained from a search considering all the combinations of input entry and exit points.

<b>Critical circles for each entry point (considering all specified exit points)</b>
